Agglutinative Reaction and Pertussis.—Miller and Silverberg describe a new technic of tube agglutination for *Haemophilus pertussis*. Mechanical rocking of the tubes for two hours at room temperature is sufficient. A twenty-four hour growth of *Haemophilus pertussis* is used. The small amount of serum required (0.1 cc.) may be collected in a Lyon tube by ear or toe puncture. The serums from ten of 101 children with negative histories for pertussis produced agglutination, but in children less than 5 years of age the agglutinative titers in the positive serums were not higher than 1:20. The serums from 161 of 164 children who had been injected with phase I *Haemophilus pertussis* vaccine produced agglutination. The titers of the positive serums were in general high, usually 1:160 or higher. Second and occasionally third specimens of serum were obtained at wide intervals up to thirty-eight months after vaccination and these showed a tendency to maintain their titer. The serums from fifteen of seventeen children with pertussis produced agglutination at some time during the disease. The titer of agglutination attained was extremely variable and seldom more than 1:160. The serums from thirty-six of sixty-seven children who had recently recovered from pertussis produced agglutination. On retesting after intervals of several months consistent decreases in titer were observed. Many serums had become negative though occasional serums produced agglutination up to twenty-five months after the onset of the disease.

Phenolphthalein Eruptions.—Sandler discusses phenolphthalein eruptions and reports three such cases, one of which leads him to believe that phenolphthalein is present in the skin in the early stage of the eruption. The author finds no reference to a similar observation in the literature. It has been stated that except for the ingestion test no other forms of testing have been evolved which are of value in the diagnosis or prognosis of existing hypersensitiveness to the drug. The author shows that the oral administration of a small dose (0.0065 Gm.) of the suspected drug is the best method of determining the causative agent. In his cases, in about one hour after its administration, edema of the lips with deep seated vesicles occurred and the hue in the fixed phenolphthalein lesions was greatly accentuated.

Cobra Venom for Intractable Pain.—Rutherford used cobra venom for the relief of intractable pain in seventeen cases, generally because of terminal cancer. It is important that the drug be given intramuscularly, for if it is given subcutaneously it will cause local redness and tenderness for several days. At the beginning of the series, treatment was started with an injection of 0.5 cc. (2½ mouse units), followed by daily injections of 1 cc. (5 mouse units). Later the author endeavored to adjust the initial dose to the requirements of the patient, beginning in some cases with 2 or 3 cc. (10 or 15 mouse units) and continuing the dosage at that level for from four to six days or until complete relief was obtained, and then considerably lowering the dose to a maintenance level. Eight of the seventeen patients (46 per cent) considered themselves completely relieved. Four of the group (24 per cent) estimated their relief at from 75 to 95 per cent. Three (18 per cent) estimated their relief at from 50 to 75 per cent. In only two did the amount of relief fall below 50 per cent. In other words, nearly 50 per cent of the patients were completely relieved of pain and in 88 per cent the relief was 50 per cent or more. If there is a response it usually begins on the third or fourth day of injection, despite the amount used, and is complete by the sixth or seventh day. The benefits are not

likely to increase after that time, but the relief of pain is likely to continue at that level, even though the amount of cobra venom is reduced to a maintenance level, determined by the patient. The majority of patients were able to maintain their relief on one ampule every other day or one a day, although several required two or three a day. There were no side reactions and there was no evidence that increasing amounts of the drug were necessary. The drug seemed to act on pain no matter what its etiology. When relief from pain is obtained the mental outlook and general health of the patients are benefited by release from the sharp drag of constant pain. Some patients are able to return to their work and to become wage earners again. In those who are only partially helped, the drug makes an excellent basal analgesic which can be augmented by analgesics that are not habit forming. This avoids the danger of morphine addiction and increasing opiate tolerance. For those patients who are not helped, intrathecal alcohol injection or chordotomy should be considered. Since cobra venom can be self administered, it makes an ideal outpatient treatment or treatment which can easily be followed by the general practitioner in the nonhospitalized case. There is no evidence of danger of addiction, increasing tolerance or toxicity of the drug.

Autohemotherapy and Hyperpyrexia for Rheumatic Disease.—As an increase in the body temperature is a natural defense mechanism, it occurred to Ishmael that the artificial fever may reinforce the reaction of the injected blood (autohemotherapy). Based on this idea he applied these measures to 168 rheumatic patients. From 10 to 20 cc. of blood was withdrawn and immediately re injected into the muscles of the hip. This is done before clotting takes place and nothing need be added to the blood. The artificial fever is instituted immediately following the autotransfusion and a temperature of 101.5 F. for one hour, the inductotherm being used for adults and intravenous typhoid vaccine for children. With inductothermy, approximately one hour was required to reach 101.5 F.; this temperature was maintained for one hour and about two hours was necessary for the temperature to return to normal. Patients were allowed to eat a normal meal before the fever was started and occasionally from 10 to 25 grains (0.65 to 1.6 Gm.) of sodium chloride was supplied along with ample fluids. No untoward reactions have been experienced and

patients resume their normal activities when the temperature returns to normal. Optimal results were obtained when the procedure was repeated every four days. In the average case, from six to ten treatments were given. The most striking results were obtained in acutely inflamed joints. Forty-four such cases were treated by this combined rapid desensitization method and all responded completely in an average of seventy-six hours. In none have there been any recurrences. To date the types of joints treated in the acute phase included seven of acute gonococcic arthritis, two of acute gouty arthritis, fifteen of acute infectious (atrophic) arthritis and twenty diagnosed as acute fibrositis. All these cases were in the acute phase and not chronic exacerbations. In the acute gonorrheal cases the urethritis had to be treated by other measures after the joint and sedimentation time had returned to normal. Twenty patients with rheumatic fever received artificial fever of 104 F. for an average total of eight hours; fifteen had complete remission and five "improved." Those receiving only autohemotherapy or fever of 101.5 F. or less failed to improve. Of ten patients with chronic infectious arthritis given combined therapy, one had a remission in four weeks, four were improved, five had no effect and none suffered an exacerbation. Three others given fever only (101 F. for one hour) had no remissions, only one improved and there were no exacerbations. Three similar patients given only autohemotherapy had no remissions, two "improved," the condition of one remained unchanged and none flared up. Thirteen patients diagnosed as having chronic fibrositis received the combined therapy, fifteen only the fever and two the autohemotherapy only. Twelve of the thirteen had a remission and one was improved. Fourteen of the fifteen had a remission and one was improved. Of the two receiving only the autohemotherapy the group diagnosed as having hypertrophic arthritis (menopausal arthralgias) the main effects of the autohemotherapy seem to be in the delayed absorption afforded by the presence of the blood. In the thirty cases exhibiting rheumatic exacerbations, from three to five days prior to and during each complete remissions were seen in twenty-six of the thirty cases treated. Three were "improved" and one was unimproved. Nine women received the combined therapy, eight have complete remission and one was "improved."

Roentgen Therapy for Pneumonia.—The results obtained with roentgen therapy in eighty-eight cases of acute pneumonia seen during a period of one year at the Niagara Falls Memorial Hospital, Scott believes, indicate that there is a definite field for this type of therapy. Whenever possible the patient

was treated immediately on admission to the hospital and before being taken to his room. The factors used were 75 kilovolts, 3 mm. of aluminum filter, 200 roentgens, an open lead glass bowl type of tube holder with a 15 cm. opening centering over the area of chief consolidation (determined by a previous roentgenogram) without a cone or other method of screening off the rest of the chest. In bronchopneumonia the treatment was usually centered over the area which showed most confluence of mottling but without exclusion of the entire chest. The ages of the patients varied from 3 weeks to 76 years. In the patients who passed through the x-ray department the mortality rate was approximately 4 per cent lower than the general hospital pneumonia death rate for the twelve months under consideration. Also there was a marked difference between the patients who were given roentgen therapy and/or roentgenographed for diagnosis and those who did not visit the x-ray department at all; that is, the difference between 19.5 (including the eighty-eight patients who were given roentgen treatment and fifty of whose chests roentgenograms only were taken) and 44.1 per cent. Patients frequently look better and feel better within a short time after the treatment. It frequently happens that a definite fall in temperature occurs in from twelve to twenty-four hours after treatment, subsequently followed by a rise or occasionally by a rise showing two peaks, but then the temperature may proceed rather rapidly to normal. If the patient appears better, whether the temperature shows an abrupt drop or not, his clinical appearance is considered rather than temperature record and he is not treated for two or three days unless there seems to be need for it. Often by this time the temperature is going down and no further treatment is necessary. A second treatment was needed in only a few cases. The rapid improvement in the condition of most patients who had roentgen therapy early was frequently startling. Averaging the eighty-eight cases, a death rate for all cases in which any type of roentgen treatment was given, no matter what else was done, was 19.3 per cent. The average hospitalization time for the 138 cases of pneumonia was 15.9 days for males and 13.9 days for females. The hospital time of a patient treated chiefly by roentgen therapy was definitely shorter than the time required by one receiving roentgen and other methods of treatment; approximately one half the time. If the length of hospitalization is cut in half, certainly the cost to the patient is cut. The frequency of complications definitely seemed to be lessened. As long as the patients were even roentgenographed the death rate was lower; as compared to patients not even roentgenographed the percentage in favor of some form of roentgen therapy seems almost incredible. Contraindications appear to be nil, whereas other types of medication, especially serum, may be definitely contraindicated. Any other treatment desired by the attending physician may be given in conjunction with roentgen therapy. No reactions to the treatment were observed. Further reports on this problem are necessary to estimate accurately the value of roentgen therapy for pneumonia.

Sacro-Iliac Changes in Spondylarthritis.—After reviewing 153 cases of ankylosing spondylarthritis, some of which have been followed for many years, Forestier declares that: 1. The condition occurs rarely in women. 2. Patients frequently give a previous history of genital infection: prostate seminal vesicles or rectosigmoidal disturbances. 3. The disease has a low-grade evolution; the onset is often difficult to determine. It progresses upward from the pelvis to the cervical region and to the lower joints of the extremities. 4. The x-ray changes in the sacro-iliacs are contemporary of the early and confused low back symptoms and precede, in most cases, vertebral involvement. From these deductions the author presents a pathogenesis of the disease which he believes may explain completely its special features. He believes that the primary focus in ankylosing spondylarthritis is in the genito-urinary system or in the lower intestine and that the toxic products excreted by this focus are drained into the lymphatic system of the pelvis and from here alongside the spine. In a man, the lymphatic vessels from the prostate and the seminal vesicles pass, on both sides of the medial line, in front of each sacro-iliac joint and extend upward in the posterior part of the abdomen on both sides of the spinal column just in front of

the apophysial joints, with which they have many connections. They are directly applied on the vertebral column behind the aorta and the vena cava. In a woman, the lymphatic vessels of the uterus and the vagina follow approximately the same path and also lie near the intervertebral joints. Conversely, the lymphatic vessels of the fallopian tubes and of the ovaries are much more laterally situated in the pelvis, and when they come up into the abdomen they lie on the ventral aspect of the large blood vessels—the aorta and vena cava. Since the draining of the uterus and vagina is far easier than that of the ovaries and tubes, the infrequent occurrence of ankylosing spondylarthritis among women can be understood. This theory, the author believes, explains the slow progress of the disease, first to the sacro-iliac joints and later ascending along the different segments of the spine. The sacro-iliac joints were roentgenographically involved in more than 98 per cent of the 153 cases. From the x-ray examination of twelve cases observed in the early stages of the disease, evidence is given that sacro-iliac joints are involved previously to any changes of the spine. The reverse has not been observed.

Atypical Pneumonia with Leukopenia.—Maxfield states that recently sixty-three cases of an atypical pneumonia with leukopenia have been seen in Baylor Hospital, Dallas, Texas. These pneumonias seem to be a clinical entity. There was usually a prodromal stage of from five to ten days. The disease started with dryness of the throat and some soreness. The symptoms of a mild upper respiratory infection, general malaise and mild to severe headaches were observed. The patient became progressively worse. A rapid change with onset of fever and usually a chilly sensation then occurred.

Pain and fulness in the chest often occurred at this time. The patient's face showed anxiety and there was an elevation of temperature (from 102 to 104 F.) and an increase in the pulse and respiratory rate. There was usually a productive cough frequently accompanied by hemoptysis, which was followed in a few days by a coarse, dry, nonproductive cough which persisted even after the temperature returned to normal. This occurred between the fifth and the tenth day after admission. Although a diligent effort has been made, the causative organism has not been determined. A virus is strongly suspected. Repeated examinations of the sputum revealed acid fast organisms in only one instance and this patient had a previous history of tuberculosis. Repeated throat cultures and smears showed only normal organisms of the mouth and throat, with a gram-negative short chain nonhemolytic streptococcus in a few cases. In a few instances pneumococci were found. When these pneumococci were typed, no capsular swelling was observed with types I through XXXII of the Neufeld pneumococcus typing serum. The blood picture was that of a mild leukopenia, varying from 4,000 to 12,000 leukocytes per cubic centimeter of blood, with 82 per cent of the cases giving a leukocyte count of less than 8,000. The mononuclear leukocytes were 8 per cent or above in 38 per cent of the cases. The neutrophils varied from 40 to 80 per cent, the average being 61 per cent. A communicable factor was present, since the disease developed following contact with patients in eight nurses, four interns and three of the attending staff of Baylor Hospital. Two of the patients had a relapse, one four weeks and one three months after discharge from the hospital. The x-ray appearance of the lesions was usually infiltrative in character. They had feathery, indefinite edges with moderate homogeneous density toward their inner portions. The size of the lesions varied from those that were barely demonstrable in the roentgenograms to an almost complete involvement of both lung fields. Those cases with involvement of more than one lobe showed no increase of symptoms. There was a wide variation in the location and appearance of the lesions. Therapy was of a symptomatic and expectant nature. However, tincture of benzoin inhalations, steam inhalations, sulfanilamide, blood transfusions, nonspecific protein therapy and opiates for pain and persistent cough and the like were used. There were no mortalities. The duration of symptoms did not seem to be either shortened or lengthened by the type of treatment used. The author feels that the prognosis is good in all cases so long as the leukopenia exists and repeated bacteriologic studies fail to reveal typable pneumococci, tubercle bacilli, virulent streptococci or viruses of influenza, psittacosis or others. In the differential diagnosis typhoid, undulant fever, psittacosis, tuberculous pneumonia, influenza, influenzal pneumonia, tularemia and coccidioid granuloma should be considered.

Tularemia.—In reporting their case of tularemia, G. L. and Evelyn Powers wish to call attention to the fact that the disease occurs in all parts of the United States. They believe that theirs is the first case in which treatment with sulfanilamide and antiserum was successful.

Angina Pectoris and Tobacco Smoking.—Three patients exhibiting the syndrome of angina pectoris caused by smoking were seen by Birk and Huber. They obtained electrocardiograms when the patients sought relief from their symptoms and again when the underlying offending factor (smoking) was removed, after which the electrocardiograms were normal and the patients felt well. The changes noted in the electrocardiograms were definite. One of the patients with angina pectoris caused by tobacco smoking was a woman.

Puerperal Sepsis and Hemolytic Streptococci.—Since evidence is accumulating that the upper part of the respiratory tract of the patient herself or her contacts is the most probable source of puerperal infection with hemolytic streptococci Fleming, with a view of preventing the transfer of these organisms to the genital tract of pregnant women immediately before, during and after childbirth, determined the incidence of group A hemolytic streptococci in 120 women medical students before they began their work in the maternity wards of the obstetric and gynecologic unit of the Royal Free Hospital. In each case the throat swab was taken about three weeks before the student was due for her two and a half months of resident training in the hospital. If a growth of streptococci was found, McLeod's test was carried out to see if it showed soluble hemolysin, and, if it did, the Lancefield group to which the hemolytic streptococci belonged was ascertained by the precipitin reaction. A growth of hemolytic streptococci was obtained in 22.5 per cent of the cases. In only five of the 120 students examined—that is, in 4.2 per cent—did the hemolytic streptococcus belong to the Lancefield group A. The series, spread over two years, gave no evidence of any seasonal variation in the frequency of the carrier rate of all hemolytic streptococci or of Lancefield group A. There was no evidence of any relation between the incidence of hemolytic streptococci in the throat belonging to group A and the presence of tonsillar tissue. Complete tonsillectomy had been performed in about 50 per cent of the students. Hemolytic streptococci were absent in as large a proportion of students with tonsils or remnants of tonsils as of those in whom complete tonsillectomy had been performed. Each student with hemolytic streptococci was given leave of absence, and moderate exercise in the open air, painting or gargling of the throat or the administration of sulfanilamide compounds was recommended. Whenever it ceased to be possible to grow group A streptococci from their throat swabs the students were considered fit to begin their residence. The time required for treatment varied, but the persistence of the positive throat swab was noticeable in those students whose nasopharynxes were in an unsatisfactory condition. From an inquiry into the medical work previous to obstetrics there seems ground for the suggestion that the curriculum of medical students should be so arranged that work in the children's wards should not immediately precede or be contemporary with work in obstetrics unless special steps are taken to control the carrier rate in the children's wards. Those in contact with respiratory ailments should exercise particular care, with the knowledge that their own susceptibility to act as carriers of group A hemolytic streptococci may be an important factor in the transmission of the infecting organism of puerperal fever. Only on four occasions during these two years, when throat swabs were examined because puerperal pyrexia had developed in a patient, were hemolytic streptococci found in the patient's throat. The same strain of hemolytic streptococci was isolated from the cervix of one of the patients and also from the throats of a student and a nurse in contact. In only one of the other cases was a student found to be a carrier. It appears that routine examination of throat swabs of the medical and nursing staffs is indicated.

Sulfanilamide for Scarlet Fever.—Since January 1937 Benn treated 256 patients with scarlet fever with sulfanilamide (Bayer), and 261 control patients were simultaneously treated

without the drug. Antiscarlatinal serum was given to those patients in both groups who were thought to require it, irrespective of the sulfanilamide. It was realized that sulfanilamide has little or no effect in the acute febrile stage of scarlet fever, except perhaps in patients with a frankly septic type of the disease; therefore it was thought that the incidence of complications (which occur more often in children less than 10 years of age) would probably give the best indication of the value of the drug. The general treatment of the patients did not differ in the two groups. The amount (divided into three equal doses in twenty-four hours) of sulfanilamide, after a previous trial period, was fixed at 0.75 Gm. for children less than 2 years of age, 1.5 Gm. for children from 3 to 7 and 3 Gm. for those from 8 to 10. Administration of the drug was continued until the temperature had been normal for a week in uncomplicated cases. If complications developed, administration was prolonged for as long as was indicated. Signs of sulfanilamide toxemia were seen infrequently and in no case gave rise to anxiety. All patients suffered from simple scarlet fever, and no death occurred in either series. The early acute stage of scarlet fever seemed to be uninfluenced by sulfanilamide except in cases in which some septic element was apparent: The subseptic patients appeared to benefit from the drug. There were a total of forty-eight complications in the test group as compared to eighty-one in the control group. Individual complications, with two exceptions, showed a greater frequency in the control group than in the test group, and certain complications, including rheumatism, endocarditis and myocarditis, were absent from the test series but present in the control cases. The incidence of suppurative otitis media was greater in the control series than in the test series, 10.3 and 6.3 per cent, respectively. It appears that an important action of sulfanilamide in the mild type of scarlet fever is prophylactic in that it lowers the incidence of complications. For this reason seventy-nine patients have been given 1 Gm. of sulfanilamide daily, in four equal doses, from admission until the fourteenth day and again from the twenty-first to the twenty-eighth day. The results in these seventy-nine are sufficiently good (there were only four cases of suppurative otitis media, two of adenitis, two of paronychia and one of albuminuria) to encourage further prophylactic trial. The most striking effect is the comparative absence of the many minor septic sequelae. Cyanosis was not encountered in this group, but a maculopapular erythema of morbilliform type, which first appeared on the extremities, then on the face and finally on the body, occurred in two cases. In one patient this was accompanied by pyrexia, which subsided within forty-eight hours after the drug was withdrawn. No other toxic effects were encountered.

Sodium Diphenyl Hydantoinate in Epilepsy.—Williams decided to try treatment with sodium diphenyl hydantoinate in ninety-one patients with chronic epilepsy who had ceased to respond to other anticonvulsants. The patients all lived at home and had been under regular observation and treatment with other drugs for an average of 6.4 years. The longest continuous period of treatment with sodium diphenyl hydantoinate was ten months and the shortest six weeks, the average duration in eighty-three cases being 4.1 months. Sodium diphenyl hydantoinate was given in capsules of 0.1 Gm. An initial daily dose of 0.2 or 0.3 Gm. was slowly increased, and 0.6 Gm. daily was given in some cases. Phenobarbital and bromides were continued in decreasing doses during the period of substitution, and it was sometimes necessary to reduce the dose of sodium diphenyl hydantoinate and to supplement it with other anticonvulsants. After trial of the drug alone the following medications were found to give an optimum therapeutic effect: sodium diphenyl hydantoinate alone in fifty-two cases, combined with

phenobarbital in nine cases, with bromides in sixteen cases and with phenobarbital and bromides in six cases. As a result of this treatment the fits were reduced in frequency in 79 per cent of the subjects with grand mal and in 63 per cent of those with petit mal. In 19 per cent the improvement was dramatic and has been maintained for over five months. Toxic symptoms arose in 36 per cent, and two patients died in status epilepticus while receiving the drug. The drug seems to be of value in the treatment of epilepsy in some cases when other forms of treatment have failed, but there are no indications that it should supersede the less toxic anticonvulsants in the initial stages of treatment. Its administration requires careful observation of the patient.

Stilbestrol and Anhydro-Oxyprogesterone in Menstruation and Lactation.—Wenner and Joël say that although all investigators agree about the similarity of the properties of stilbestrol to those of the estrogenic hormone, emphasis is constantly laid on the yet unresolved question of dosage. They sought to ascertain (1) the minimal dose necessary to produce proliferation in a resting or atrophic endometrium, (2) the dose necessary to induce a hyperproliferation (in the sense of glandular cystic hyperplasia), and (3) the doses necessary to prevent and to inhibit lactation in the puerperium. At the same time they tried to ascertain the oral dose of corpus luteum hormone (anhydro-oxyprogesterone) necessary to produce the stage of transformation of the endometrium with subsequent menstruation. The authors studied the effect of stilbestrol and of anhydro-oxyprogesterone on the endometrium of one woman who had attained the climacteric thirteen years earlier and on eight women who had been castrated by means of roentgen treatments two or three years previously, when they were over 45 years of age. Each woman was subjected to three curetages: one before treatment was begun, the second after the administration of stilbestrol and the third after treatment with anhydro-oxyprogesterone. They found that in order to obtain proliferation of a resting or atrophic endometrium, it is necessary to give 25 mg. of stilbestrol by mouth or 15 mg. by intramuscular injection. If from 50 to 60 mg. of stilbestrol is given by mouth, a glandular cystic hyperplasia can be produced. The stage of transformation and the menstruation following proliferation can be produced by the oral administration of from 220 to 300 mg. of anhydro-oxyprogesterone. In only two cases did the administration of stilbestrol cause slight secondary symptoms, and even these disappeared rapidly. In the second part of this report the authors describe their studies on the effects of stilbestrol on lactation. Since several investigators had succeeded in either preventing the influx of milk or inhibiting lactation by the administration of estrogenic hormone, the authors decided to use stilbestrol for the same purpose. In six cases (four stillbirths, one case of tuberculosis and one of depressed nipples) they administered stilbestrol on the first day after confinement to prevent the secretion of milk. In three of these cases one tablet (5 mg.) was given and in the other three, two tablets (10 mg.). The treatment was successful in all of these cases; no milk was secreted, and the breasts remained flaccid. In fourteen cases stilbestrol was given to inhibit established lactation, the indications being hypogalactia, bleeding fissures, mastitis, eczema of the breasts and tuberculosis. It was found that to arrest lactation, from 5 to 10 mg. of stilbestrol is usually effective, but in some cases larger doses are necessary (not more than 20 mg.). All women took stilbestrol without difficulty, and no secondary symptoms were observed.

Tumor of Left Frontal Lobe: Case. Hélène Weiss.—p. 297.

New Conceptions on Essential Epilepsy.—According to Wertheimer, the term essential or idiopathic epilepsy does not designate a nosologic entity but is generally applied to all cases of epilepsy in which neither the clinical examination nor the history reveals exogenic factors as cause of the attacks. He concludes that essential epilepsy is a sequel of obstetric intracranial lesions, especially of intracranial hemorrhages, which may have escaped observation because their symptoms were slight. Intracranial hemorrhages are often caused by the use of forceps, that is, in extremely retarded deliveries, but they occur also as sequels of extremely rapid deliveries. Studies on the course of labor in epileptic women revealed a high incidence of the precipitate type of deliveries. Thus the infants from epileptic mothers are especially predisposed to intracranial hemorrhages and their consequences. The author shows that this circumstance may give rise to the familial and apparently "hereditary" appearance of epilepsy. However, he maintains that a hereditary epilepsy in the biologic meaning of the term "hereditary" does not exist, the apparent heredity being a result of a vicious circle. After giving the clinical histories of five children he stresses that, as a result of the dorsal position of the nursing, the blood discharged during the cranial hemorrhages settles in the occipital region and remains there like a foreign body until it gradually becomes organized, which may require several months. The cicatrization resulting from this process may produce epileptic attacks. The ventral position of the nursing, on the other hand, facilitates cranial circulation, favors the resorption of the sanguine effusion and thus avoids the cicatrization and the subsequent epilepsy. Placing the nursing in the ventral position is a prophylactic measure against the frequently disastrous sequels of obstetric meningo-encephalic hemorrhages.

Hepatic Glycogen in the Newborn.—Fopp studied the glycogen content and distribution in late fetal and neonatal livers in eighty cases: twenty-four fetuses with an intra-uterine existence from seven to nine months, the remainder (fifty-six) consisting of infants either stillborn or dying within the first twenty-four hours. The majority of the necropsies were performed during the second or third day on bodies kept in refrigeration. Portions of the liver 0.5 cm. in thickness were steeped in a 95 per cent solution of alcohol, embedded in celloidin and tinted according to the Bestsch method. In addition, control analyses were made on fifteen infants who had died within the first month. The results obtained showed glycogen content in the combined late fetal and neonatal livers (eighty) in the following proportions: no glycogen 26 per cent (twenty-one), little glycogen 24 per cent (nineteen), intermediate group 25 per cent (twenty), much glycogen 25 per cent (twenty). The glycogen content for the fetal group taken by itself (twenty-four) indicated about the same percental proportion as for the combined group: no glycogen 21 per cent (five), little glycogen 29 per cent (seven), intermediate group 25 per cent (six), much glycogen 25 per cent (six). These results warrant the inference, confirmatory of the studies made by others, that the glycogen content is often high in fetal livers but give no support to the assumption that high glycogen presence is the "norm." In comparison with the data obtained for the livers of unslected healthy adults accidentally killed, the glycogen content was more frequent and pronounced. On the other hand, tests on the fifteen controls clearly indicated

loss of glycogen, only five attaining to intermediate and high rating. These indications, according to the author, point to a special stability of glycogen retention in neonatal livers and were confirmed by consecutive testings especially made on the liver of another newborn infant at intervals between one and one-half and forty-eight hours. Morphologically, the author finds a close analogy between the glycogen in fetal and neonatal livers and that of adults, with the exception of a complete absence of nuclear glycogen, which he accounts for by the absence of acidosis. Observations made on the hepatic cells of adults could be verified in the livers of the newborn. Evidence for glycogen distribution in the lobule was too conflicting to admit of generalized inferences. Differences between neonatal and adult livers may be due to pathologic processes in adult livers. The author does not seek to explain the great loss in the glycogen content of neonatal livers on a uniform basis. Factors such as prolonged labor, intra-uterine antepartum death, premature detachment of the placenta, febrile infection, marked fatty degeneration and blood congestion in the liver, causing enlargement of the central veins and capillaries, may all cause glycogen impairment while congenital goiter, thymus hyperplasia, sex and the number and size of hemopoietic hepatic centers, except in fetal myeloblastosis, seem not to affect the glycogen content. The evidence for the effect of the size of the liver on glycogen is too meager to justify conclusions.

*Effects of Ketogenic Diet. M. Julez and E. Winkler.—p. 807.
Diazotization Speed of Blood Serum. A. Gigon and M. Noverraz.—p. 811.

Ketogenic Diet in Asthma.—Julez and Winkler studied the effects of a ketogenic diet on fourteen patients (twelve asthmatic) with four healthy persons as controls. Concluding from earlier experiences of their own and others that neither acidification nor dehydration was the key to the problem, the authors turned from investigating the bicarbonate content of the blood to the analysis of ammonia secretion, with the purpose of obtaining a better insight into the metabolic disturbances caused by asthma and into the processes whereby effects are secured through a ketogenic diet. The conditioning of the controls included a standard diet, administration of phosphoric acid, a ketogenic diet for from one to two weeks and repeated tests for ammonia and alkali reserve. In their preliminary assays the authors discovered, on the average, no quantitative difference in ammonia secretion between the controls (650 mg.) and the asthmatic patients who had been put on a standard diet for three days (630 mg.); according to the literature ammonia elimination varies between 400 and 600 mg. Neither did phosphoric acid have any appreciable effect on the daily quota of ammonia excretion. In their study of the effect of a ketogenic diet on ammonia excretion the authors found that in the non-asthmatic controls ammonia elimination during the ketogenic diet was increased by 45 and 50 per cent as compared with the standard diet, continued for from one to two weeks with acetoneuria and then decreased, at which time not even increased ketosis could enhance ammonia excretion. The authors differentiate four kinds of ketogenic diet effect on ammonia secretion of asthmatic patients: 1. In patients with normal ammonia secretion under conditions of normal diet, the ketogenic diet increases ammonia secretion considerably. 2. In patients in whom absolute ammonia elimination is normal, the ketogenic diet does not increase it. 3. In patients whose ammonia elimination on a standard diet is subnormal, the ketogenic diet considerably increases it. 4. In patients whose ammonia elimination is subnormal, the ketogenic diet does not affect it. A ketogenic diet was found effective only in patients belonging to groups 1 and 3. Those in groups 2 and 4 were patients affected with serious forms of asthma and were not benefited by the ketogenic diet. In their investigations of the ketogenic diet on the alkali reserve—the latter being defined as the sodium bicarbonate content in the plasma expressed in cubic centimeters of carbon dioxide obtained from 100 cc. of plasma—the authors ascertained that the ketogenic diet diminished the alkali reserve both of

asthmatic and of nonasthmatic persons by from 1 to 20 per cent. The exceptional detection of an increased alkali reserve after from one to two weeks of the ketogenic diet, amounting in one case to 24 per cent, is explained by the authors on the assumption that the organism, under the influence of the ketogenic diet, adjusts itself so much to neutralizing acidity by means of ammonia that after a time it impairs its power to neutralize with bicarbonate. They appeal for confirmation of their assumption to the results obtained from the phosphoric acid administration during the conditioning period and to the abnormal reaction of some of the asthmatic subjects.

*Abdominal Syndromes from Adenopathies of Mesentery. A. Parini.—p. 314.

Abdominal Syndromes from Mesenteric Adenopathies.—According to Parini there are certain acute forms of adenopathies of the mesentery with symptoms simulating those of acute appendicitis and also forms with abscess formation and possible rupture of the abscess and consequent peritonitis. The condition is generally found in children and adolescents, although it may be seen in adults. The enlarged mesenteric lymph nodes can be felt by palpation only in rare cases. The differential diagnosis of mesenteric adenopathies with acute appendicitis is made from the type of pain, which is of an intermittent character and located in the ileocecal or periumbilical region rather than in the appendicular region. The presence of leukocytosis with lymphocytosis is of diagnostic value. Mesenteric adenopathies may be secondary to tuberculosis, chronic inflammation of certain abdominal organs, or else chronic infection of the throat, teeth, respiratory tract or intestine. The treatment is etiologic, namely chemotherapy, especially sulfanilamide, in infection and medical, physical and other treatments in tuberculous adenopathies. In the latter the treatments indicated are administration of iodide, exposure of the patient to sun irradiations, administration of roentgen irradiations, sojourn of the patient in the proper climate and proper diet and general hygiene. Surgical intervention is indicated only in acute forms in the presence of (1) intestinal obstruction or stricture from compression of the enlarged lymph nodes or from adhesions, (2) acute suppuration, especially if there is a menace of rupture of a lymphatic abscess, or (3) peritonitis from rupture of an abscess. It is advisable to establish ample drainage after the operation. It is also advisable to resort to surgical intervention only in the specified conditions mentioned, since removal of enlarged lymph nodes may be followed by production of hemorrhages or development of necrosis, suppuration or formation of adhesions. Five cases of either the tuberculous or the infectious etiology are reported by the author.

*Treatment of Open Fractures. A. Chintellino.—p. 283.

Treatment of Open Fractures.—Chintellino has treated more than fifty cases of open fractures in the course of the last four years. The group included open fractures of the large bones (with exposure of the articular cavity in some cases) and open and comminuted cranial fractures. There were some diabetic and old persons in the group. The treatment, a modification of Böhler's, consists of surgical disinfection of the soft parts of the wound and of the bone tissues followed by complete suture of the wound. The operation is performed in the following manner: General care is given to the patient to prevent development of traumatic shock. The local region of the skin is sterilized with iodine (without any previous irrigation on the wound and nearby tissues). Anesthesia by infiltration is abundantly administered by using a 0.25 per

thousand solution of nupercaine. A roentgenogram of the fracture is made. All contused and contaminated tissues of the wound are removed and the edges of the wound are cleansed and made regular. The bone fragments are surgically disinfected, the small fragments are removed and those of moderate and large size are replaced. Ligation is done only when there are sectioned nerves or sectioned blood vessels. No foreign matter (of osteosynthesis or sutures) is left in the focus of the fracture. The skin is then sutured with silk stitches. In some cases it is advisable to leave one or various draining tubes. If so, they are placed in an inclined position. In fracture is then reduced and the limb immobilized in a cast with a window over the wound. In some cases transskeletal traction can be resorted to for the first twenty days, after which the fracture is managed as a closed fracture. In some of the author's cases the articular cavity was open and was treated by detersion with swabs soaked in ether. Cranial fractures were complicated in four cases by opening of the frontal sinuses, which were properly treated during the operation. Osteomyelitis of the bone fractures did not take place in any case, the process of healing was uncomplicated and both healing and regaining of use of the limb took no longer than when treated by any other method employed in open fractures. The author considers this the treatment of choice for open fractures.

Catabolism of Blood in Hypertension.—Bock and Weyand studied the exchange of the blood pigments of patients with pale hypertension, in whom the renal function was impaired, and in those who had transitional forms from red to pale hypertension. They employed Heilmeyer's method, which determines the urobilin elimination per hundred grams of circulating hemoglobin and designates the result as the "index of urobilin catabolism." However, they complemented Heilmeyer's method by determination of the resistance and by measuring the median diameter and the volume of the erythrocytes, the thickness determined the iron content of the serum and bone marrow and examined myelograms and the circulatory conditions. Summarizing their observations they say that five cases of malignant nephro-angiosclerosis (Volhard's pale hypertension) in which there was an average blood pressure of 213/129 mm. of mercury and with typical angiospastic retinitis showed a noticeable increase in the catabolism of the blood. The total mass of erythrocytes was decreased but the plasma was increased. The values for hemoglobin, erythrocytes and the color index indicated anemia. The erythrocytes were pale and thin; their volume was reduced although the plane diameter was normal. Since the increased catabolism of the blood was accompanied by only a slight increase in the percentage of reticulocytes and since they were all comparatively old cells with vital granulation, the authors assume rapid aging of the reticulocytes and a retarded elimination from the bone marrow. The tendency toward augmentation of the index of urobilin catabolism and toward the reduction in the total quantity of erythrocytes was the greater the more severe was the impairment of the renal function. In seven patients with an average blood pressure of 192 systolic, 98 diastolic who, on the basis of the changes in the fundus oculi, had to be regarded as belonging to the group with transitional forms from red to pale hypertension, the catabolism of the blood was found to be near or noticeably above the upper limits of normality. The total mass of erythrocytes was decreased, but there was hardly any compensatory increase in plasma and no increase in the total quantity of blood. In contradistinction to the patients with pale hypertension, these patients with the

transitional forms show no impairment of the hemoglobin content or the erythrocyte count. Their erythrocytes resemble morphologically those of the patients with pale hypertension. The reticulocyte numbers are higher and there are more young forms than in typical malignant sclerosis, that is, the compensatory functions are more favorable. In a patient with red hypertension in whom the pressure was 180/90 and the renal function good, the blood exchange was near the upper limit of normality and the mass of erythrocytes and of plasma was normal. There was no anemia and the percentage of reticulocytes was normal, as was also the form of the erythrocytes. Three patients with chronic glomerular nephritis with an average blood pressure of 160/88 and with a normal fundus oculi showed a greatly increased hematic catabolism, like the patients with nephro-angiosclerosis, and a greater reduction in the total mass of erythrocytes and plasma. The anemia of these patients was more severe than that of patients with malignant sclerosis, although the retention of urinal substances was less or even lacking. The authors believe that the factor which is most important for an increase in the catabolism of the blood is not the impairment of the erythrocytes in the presence of contracted vessels but rather the retention of urinal substances. They found that the greater the increase in indican, the greater is also the index of urobilin catabolism. To be sure, observations in several cases of nephritis and malignant sclerosis indicate that the factor of "renal insufficiency" is not necessarily delayed until after the indican test of the serum is positive. The author observed an increase in the catabolism of the blood and a decrease in the mass of circulating erythrocytes even in the absence of indicanemia. In cases of chronic nephritis the increased hematic catabolism was accompanied not only by an insufficient replacement of erythrocytes (as in cases of malignant nephrosclerosis) but also by an inadequate restoration of plasma.

*Investigations on Hormone of Lactation of Anterior Lobe of Hypophysis. K. Ehrhardt and H. F. Voller.—p. 19.
Investigations on Modification of Structure of Thyroid by Vitamin C. M. Schöber.—p. 24.

Lactation Hormone of Anterior Lobe of Hypophysis.—The investigations presented by Ehrhardt and Voller concern the presence of the hormone of lactation in the blood and urine. The hormone was extracted according to the method of Lyons and Page and was injected under the skin of the crop of young pigeons. In contradistinction to other investigators, the authors did not regard the appearance of so-called crop milk as indicator, but rather the microscopically demonstrable hypertrophy of the cutaneous papillae of the crop and the formation of secondary papillae. They first examined specimens of blood and urine, which were obtained from nulliparous women who had a regular twenty-eight day cycle. Further they investigated the occurrence of the lactation hormone in pathologic processes, such as abortions, and finally they tested the action of the hormone of lactation in guinea pigs. Summarizing their results, they point out that the occurrence of the hormone of lactation in blood and urine shows two maxima in the course of the menstrual cycle, one at the onset of menstruation and one at the time of the rupture of the follicle. Investigations in connection with the hormone of lactation appears in especially large quantities during processes of decomposition in the genital organs. In pregnant guinea pigs the hormone was found to have an abortifacient effect, but it was also possible to influence the inammary glands of pregnant guinea pigs in that they were brought prematurely into that stage which physiologically coincides with the "shooting in" of the milk. The authors suggest that the hormone of lactation not only exerts a specific action on the mammary tissue but probably has functional significance also in the menstrual process. This raises the question of the relationship of the hormone of lactation to the estrogenic hormone and to the corpus luteum hormone. The authors found that the hormone of lactation appears when the action of the two other

hormones ceases, which would seem to indicate that the processes in the female genitalia are influenced not only by the estrogenic and the corpus luteum hormones but at times also by the hormone of lactation. On the basis of their observations the authors suggest that lactation hormone of the anterior lobe of the hypophysis acts not only on the mammary gland but at times also on the ovary and the uterine mucosa in that it is involved in the rupture of the follicle and in the menstrual decomposition of the uterine mucosa.

Myelogenic Osteopathy.—Markoff directs attention to recent advances in the knowledge on the relationship between osteal and medullary structure and functions, pointing out that the intravital examination of the bone marrow according to Arinkin's method permits an evaluation of the morphology and function of the medullary tissue. A comparison of the osteal structure and of the morphology and function of the medullary tissue shows a coupling between medullary and osteal changes under physiologic and under pathologic conditions. This connection is designated by the author as the medullary-osteal relation. Functional activity and morphologic aspects run parallel under physiologic conditions, though a study of the various forms of osteopathy reveals a diverging development between osteal and medullary changes. The author gives his attention to the medullary-osteal relationship in various forms of osteopathy. He demonstrates that in osteoporotic processes the marrow is not atrophic and hypo-active but rather hyperplastic and hyperactive. In studies on different forms of osteopathy, he shows that the myelogenic factor is of decisive influence in the pathogenesis of these forms of osteopathy. If the functional relationship between the medullary and osteal tissues is impaired, there develops a syndrome which can be designated as myelogenic osteopathy. The author thinks that the syndrome of myelogenic osteopathy represents a proof of Naegeli's hypothesis of the medullary origin of osteomalacia. He further shows that the idea of hematic dysplasia, which Gänsslen formulated for the age of growth, applies in a slightly different form also to adults, except that here there is not a single functional direction from bone marrow to bone but relations between cellular marrow and osteoporosis and between fibrous marrow and osteosclerosis.

Blood Picture During Alarm Reaction.—Dalton and Selye say that it has been shown that acute damaging stimuli (such as exposure to cold, muscular exercise, toxic doses of drugs, hemorrhage and surgical intervention) elicit a group of typical symptoms. The most characteristic among these are enlargement of the adrenal cortex with a decrease in its lipid content, loss of chromaffinity of the adrenal medulla, acute involution of the thymus, the lymph nodes and the spleen, formation of ulcers in the gastrointestinal tract, hemoconcentration, and characteristic changes in the chemical composition of the blood. The fact that, irrespective of the type of damaging agent, the resulting symptoms are always approximately the same, led to the conclusion that they are merely the somatic expression of the response of the organism; that is, a hitherto unrecognized generalized reaction of the body. These considerations, and the fact that the reaction can be elicited only by the first exposure and disappears in subsequent exposures, suggested the name "alarm reaction." Since previous investigations had shown that one of the best indexes of an alarm reaction is the blood count, the authors decided to investigate the hematologic changes of the alarm reaction in experiments on animals. They found that following exposure to an agent such as formaldehyde, which elicits a typical alarm reaction, there is an initial decrease in the total white cell count followed by an increase which is

mainly due to neutrophil leukocytosis. At the same time the red cell count rises because of the accompanying hemoconcentration. This rise may be preceded or interrupted by a transitory decrease during the first hour of the experiment. In the case of an alarm reaction produced by muscular exercise, the changes in the white cell count are similar to those elicited by formaldehyde but the red cell count shows a progressive and prolonged decrease, which has not as yet returned to normal even seventy-two hours after the one hour period of exercise. During the neutrophil leukocytosis, eosinophilia develops in most cases, the eosinophils reaching their lowest level (they almost disappear from the blood) before the neutrophils reach their peak. After this, eosinophilia ensues at a time when the neutrophils are returning to normal. Reticulocytes increase in number during the alarm reaction, this increase being much more obvious after exercise than after treatment with formaldehyde. It appears that the so-called nonspecific leukocytosis, preceded by a decrease and followed by an increase in eosinophils, is a constant feature of the alarm reaction.

Gastrointestinal Tract in Lead Poisoning.—Otto and Kuhlmann first discuss the different ways by which lead can enter the human organism, mentioning absorption by the lung, the mouth and the skin. Whether the severity of the gastrointestinal disturbances depends on the mode of intake of the lead has not been determined as yet. The oral changes, although of diagnostic significance, do not greatly trouble the patient, whereas the esophageal symptoms have been known to do this. Lead esophagitis, for instance, causes retrosternal pressure, pyrosis and, in rare cases, regurgitation. Spasmodic contractions and even paralysis of the esophagus have been observed as the result of lead poisoning. Inflammatory changes of the internal wall of the stomach are a frequent symptom of lead intoxication. Moreover, gastritis and ulcers have been known to develop in lead poisoning. Reviewing the intestinal disturbances resulting from lead poisoning, the authors give their attention especially to the localization of the lead colics. They reject the generally accepted opinion that the lead colics are localized exclusively in the colon and show that the small intestine is involved. They point out that the patients often localize the spasmodic pains in the region of the umbilicus and of the hypogastrium and that the intestinal pains fail to subside after complete evacuation of the colon. The roentgenologic observations demonstrate even more clearly that the small intestine is involved. For instance, in patients with lead poisoning who were troubled with continuous and severe colics roentgenoscopy failed to reveal colonic spasms but disclosed segmental constrictions and spasms of the small intestine. Cases of definitely established ileus of the small intestine are further proof of the significance of lesions of the small intestine in lead intoxication. The authors further discuss the different modes of development of the disturbances in the small intestine. They consider (1) the direct irritation of the mucosa and of the muscular layers, (2) the irritation of Meissner's and Auerbach's plexus, (3) the impairment of the vagus and sympathetic, (4) lesions of the brain and spinal cord, (5) vascular crises and (6) increased hepatic elimination of porphyrin into the small intestine. The differential diagnosis of lead colic must consider such conditions as biliary and renal calculi, perityphilitis, pancreatic disorders, embolism of the mesenteric vessels, gastric crises and acute porphyria. In the treatment of colic of the small intestine it is necessary to differentiate between the acute and chronic forms

of lead poisoning. The severe pains of acute colic should be counteracted by opium and atropine preparations. Since vascular spasms are involved, amyl nitrite, sodium nitrite and glyceryl trinitrate are advisable. The treatment of constipation is difficult, because the purgatives may increase the intestinal pains. The authors advise against castor oil and croton oil and prefer purgative teas and salts. In case of chronic lead poisoning, removal of the lead depots by means of iodine preparations is an important factor. To be sure, this mobilization of lead may bring on acute attacks. If this is the case, the iodine therapy should be interrupted. The diet of these patients should consist chiefly of vegetables, fruits and eggs. The quantities of food should be moderate.

Ether Oil for Biliary Lithiasis.—According to Topchibashev, a pure cholesterol stone placed in a test tube containing ether became dissolved in one and one-half hour's time. Combined stones required from three to four hours. Of 120 stones experimented with, 7 per cent failed to dissolve. When sectioned, these stones displayed several layers. When the upper crust of such a stone was removed, solution of the rest took place in from three to four hours. It was further established that stones dissolved in ether vapor as well as in fluid ether. Gallstones kept in bile removed from the gallbladder of a dog did not undergo any change. Stones from the same clinical case were placed in the gallbladder of a dog and 1 cc. of ether was administered hypodermically for the next fifteen days. The stone removed at the end of the period showed definite changes and diminution in size. A control experiment showed no alterations in the appearance and size of the stone. Gallstones placed in 5 cc. of blood removed from a patient before ether narcosis showed no alteration, whereas stones of the same origin placed in 5 cc. of blood from the same patient after he had been etherized dissolved completely in the course of a few hours. Between 1933 and 1939 the author treated 150 cases of biliary lithiasis by daily hypodermic or intramuscular injections of an emulsion of 3 cc. of ether and 2 cc. of olive oil. This was continued for from fifteen to thirty days. A favorable result was obtained in 132 (88 per cent) of the cases.

Spinal Osteomalacia from Deficient Diet or Disease.—Meulengracht presents a series of three articles on osteomalacia of the spinal column. In the first one he reports observations on six patients who had lived on a diet which was more or less unbalanced and qualitatively poor or incomplete. In the second one he describes observations on eight patients who

had lived on a somewhat insufficient diet and who in addition to this had gastric achylia. In the group of patients presented in the third report the diet may have been unbalanced, but these patients are of interest especially because their histories revealed the continual use or abuse of laxatives. The osteomalacic changes were located chiefly in the spinal column. The subjective symptoms were pain in the back and loins, sometimes occurring in acute attacks. In the majority of the cases, external examination disclosed collapse of the back and in some this was associated with kyphosis. A considerable reduction in the height of the body was often noted as well. X-ray examinations revealed calcium deficiency of the skeleton, which was most marked in the spinal column. The vertebrae were narrow, biconcavely excavated or more irregularly deformed. In several cases roentgenoscopy disclosed secondary osteoarthrosis of the lumbar spinous processes due to collapse and shortening of the lumbar vertebral column. The author thinks that he is right in regarding osteomalacia as the result of dietetic deficiencies, more especially of an insufficient amount of, or an unsuitable proportion between, the calcium, phosphorus and vitamin D in the food. In this connection he cites several investigators, who pointed out that the diet of the Danish population is deficient in calcium, phosphorus and vitamin D. He believes that osteomalacia is by no means a rare disease and stresses that it must be borne in mind that, as is the case in other diseases due to dietetic deficiencies, in addition to the few manifest cases there is a large number of latent cases. Dietetic deficiencies were considered. Abnormal conditions in the digestive tract, such as gastric achylia or the abuse of laxatives, which impaired the absorptive processes, contributed to or were the chief causes of the malady. Treatment with calcium salts and vitamin D improved or banished the pain and disablement caused by the spual osteomalacia.

Cardiovascular Changes in Essential Hypertension.

Rasmussen and Thingstad examined 100 patients with essential hypertension as regards cardiovascular changes. They investigated the cardiac function, the size of the heart, the electrocardiogram, the breadth of the aorta and the calcareous deposits in the aorta and the tibial arteries. Only 8 per cent of the patients were free from pathologic changes in the cardiovascular system. The degree of cardiac enlargement and of the electrocardiographic changes was found to be independent of the height of the blood pressure. A study of the relationship between important points regarding the pathogenesis of the electrocardiographic changes in hypertension. The authors show that the four distinct types, characterized by various alterations in the QRS complex, the ST segment and the T wave. The types seem to represent different stages of the same evolution. A closer examination of the relation between these four electrocardiographic types and the cardiac enlargement revealed a strong correlation between these types and the size of the heart. Thus types I and II with comparatively small changes in the electrocardiogram corresponded to slight changes in the enlargement of the hearts, while the patients with gross enlargement of the electrocardiogram, type III ("left ventricular preponderance curves") and type IV ("electrocardiogram of the bundle branch block of the common form") had the largest hearts. Consequently the authors believe that the electrocardiographic changes described as characteristic of the electrocardiogram of hypertension are due to varying degrees of left ventricular enlargement (dilatation and/or hypertrophy) and are not due to disease of the coronary arteries. The electrocardiogram of the bundle branch block of the common type (type IV) was observed in seven of 100 hypertensive patients. An analysis of the seven cases together with another group of twenty-one cases with this electrocardiographic picture revealed that all twenty-eight cases with "electrocardiogram of the bundle branch block of the common form" were characterized by gross left ventricular enlargement. The chief cause of "electrocardiogram of the bundle branch block of the common form" (classic terminology: right bundle branch block) is supposed to be severe left ven-

Basophil Stippling of Erythrocytes in Sulfanilamide Anemia.—According to Myhre it is a well known fact that anemia may occur in connection with sulfanilamide treatment. Having observed basophil stippling of the erythrocytes in studying the blood of a woman who developed granulocytopenia after taking 19 Gm. of sulfanilamide, the author decided to examine the blood of patients with slowly developing sulfanilamide anemia for basophil stippling. In the first patient the highest count of stippled cells was 3,200 per million erythrocytes. In the second patient, a girl aged 17, who was given large doses of sulfanilamide in the course of meningitis, after having previously received it in an attack of tonsillitis, the stippled cell count reached the maximum of 6,500 per million erythrocytes. Two other patients who had received sulfanilamide for pyelitis showed a moderate increase in stippled cells (1,000 and 700 per million erythrocytes, respectively). In two other patients, in whom the total dose of sulfanilamide was unknown, the treatment having begun previous to hospitalization, the stippled cells reached a total of 3,000 per million erythrocytes. The author counted the stippled cells by means of Schmidt's method. He says that the phenomenon of stippling is an acknowledged sign of blood regeneration but that he has never seen it in connection with anemias secondary to infections but only in toxic anemias. Lead poisoning, the most common cause of stippling, could be excluded in the reported cases. In these patients, who had received sulfanilamide, the stippling was unusually fine. The stippled cells are not identical with reticulocytes but may appear simultaneously. The author suggests that the rapid increase in stippled cells (6,500) and reticulocytes observed in one of the patients may have been the result of the treatment with liver extract. He never observed stippling after the customary doses of sulfanilamide. Nevertheless, the reported cases show that sulfanilamide may have a profound influence on the hemopoietic system, even if no alarming anemia occurs.

Treatment of Pneumonia with Acetyl Sulfapyridine.—Eldahl says that of the fifty-five patients treated with acetyl sulfapyridine thirty-four were adults and twenty-one were children. *Pneumococcus* types I, III, VI, VII and XIX were found respectively in ten, five, eight, seven and five cases (21, 10.4, 16.4, 14.6 and 10.4 per cent). The average amount given adults was 40 Gm. and children 25 Gm. In twelve patients (22 per cent) the temperature dropped to 38 C. (100.4 F.) during the first twenty-four hours of treatment, in twenty-five (45 per cent) in the course of the second day. Two patients with *pneumococcus* types III and XVIII respectively died in the acute stage, with a resulting mortality rate of 3.6 per cent. The toxic symptoms were vomiting in thirteen cases, hematuria in one; whether the jaundice which occurred in one instance was due to the drug or to an acute infectious hepatitis could not be determined.

Infraclinoidal Aneurysm of Internal Carotid—Ophthalmoplegic Migraine.—Nyquist and his associates say that the accepted conception of the syndrome of ophthalmoplegic migraine as due to infraclinoidal aneurysm was expressed by the Norwegian Eduard Bull in 1877. Six cases of infraclinoidal aneurysm associated with typical symptoms are reported. In five the symptoms began with pain corresponding to the first branch of the trigeminal nerve, followed by palsy of the oculomotor

nerve. Exophthalmos was present in all but one case. One case, with bilateral aneurysm, is believed to be the fifth of its kind to be reported. The symptomatology is marked by two phases, (1) the acute episode due to rupture of the aneurysm and (2) symptoms due to pressure of the aneurysm on the neighboring structures. The history is often characteristic of a vascular disorder and suggests the diagnosis. Verification of the diagnosis depends on arteriographic, operative or postmortem establishment of the aneurysm. Treatment consists of ligation of the artery central to the aneurysm, the primary aim being to prevent future ruptures. This possibility is always at hand and the prognosis as far as life is concerned is doubtful.

- Inhibiting Action of Liquid Petrolatum in Utilization of Substances with Active Vitamin A. T. K. With.—p. 2468.

Hematuria from Sulfapyridine.—Nissen and Roesgaard state that on examination of the daily urine of forty-one patients, mostly with various types of pneumonia, all treated with sulfapyridine, hematuria was demonstrated in fifteen: macroscopically in five and microscopically in ten. In two cases the hematuria was accompanied by subjective symptoms of kidney disease (renal colic and anuria respectively). As a rule the hematuria lasted only a day or at the most a few days; there was no lasting symptom of any kidney lesion in the surviving patients. As the urine after a few days intensive treatment with sulfapyridine often changes from a dark brown to a reddish brown, a slight hematuria may easily escape observation unless daily tests of the urine are made. If the indication for continuation of the treatment is not vital, discontinuance of the drug is advised on the slightest sign of hematuria.

- *Studies on Type III *Pneumococcus* Pneumonia. G. Allsted.—p. 2523.

Type III *Pneumococcus* Pneumonia.—Alsted reports thirty cases of type III pneumonia (sixteen of the lobar form, fourteen of bronchopneumonia) treated in Bispebjerg Hospital in the same period with twenty-four cases of type I pneumonia (all lobar) and nineteen of type VII pneumonia (eighteen of lobar form, one of bronchopneumonia). He says that type III apparently predominates in women and in older persons, although the mortality rate is highest among the middle aged. In type I and type VII pneumonia two thirds of the patients were under 40. Type III is regarded as a special clinical and pathologic entity, differing distinctly from types I and VII, which generally have a less dangerous course and may be more easily influenced by specific treatment. The most rational treatment at present for type III pneumonia appears to be an energetic chemotherapy, instituted as early as possible in the course of the disease; specific therapy, however, seems to be without notable effect in bronchopneumonia.

VASOMOTOR CHANGES IN THE CORONARY ARTERIES AND THEIR POSSIBLE SIGNIFICANCE

CHAIRMAN'S ADDRESS

N. C. GILBERT, M.D.
CHICAGO

Just what might be "the nature and the cause" of angina pectoris has been a subject of interest and of varied opinion from the time of Heberden. Huchard, in the last quarter of the last century, listed some sixty-three various theories as to the cause. This list covered the possibilities so thoroughly that the only addition since that time has been that ascribing the source of pain to the esophagus and stomach—and not to the heart at all. Each theory has won adherents in its time, only to lose them again and then to revivify them in later decades. Each theory has had as its exponents some of the most distinguished physicians of the period. It may be said of angina pectoris in general what W. Townsend Porter said of the experimental work on the coronaries: "Seldom have the results of physiological studies been more at variance. The attentive reader will find no statement that is not denied, no fact not in dispute."

Today little essential difference of opinion remains. Clinicians and physiologists alike agree with Huchard's dictum: "There are not several anginas of the breast; there is only one—coronary angina." He was considering as instances of angina, however, only those cases in which definite anatomic changes in the coronary arteries could be assumed from the history and from physical examination or demonstrated at autopsy. Other cases, even though symptomatically identical, were classed as nervous, toxic or reflex. There still exists, to some extent, this same reluctance to consider as angina pectoris conditions which are apparently free from demonstrable changes in the heart or its vessels. In other than angina, attention has also been fixed on the effects of decrease in flow consequent on structural changes, and little attention has been paid to the possible effects of transient decrease in flow consequent on vasomotor changes.

The symptoms of angina pectoris result when the blood supply to the heart muscle is inadequate for its needs at that moment. In most cases this is due in whole or in part to anatomic changes in the vessels which render them unable to meet the increased demands which accompany increased work of the heart.

However, a similar disproportion between supply and demand would result if the vessels failed to increase in caliber in response to the increased needs, even though they might be adequate anatomically to furnish a sufficient blood supply. This same disproportion would result also in cases in which the needs of the muscle remained constant, increased or even decreased, but in which the blood flow was diminished in consequence of a vasoconstrictor action.

From clinical observation there is reason to assume that in some cases angina may be due to vasomotor factors which are responsible for the lack of equilibrium between supply and demand. One would have to consider a failure of the vasodilator mechanism to respond to increased needs, a failure of relaxation of the vagus tone which Rein¹ has shown to be present or, in some cases, an actual vasoconstriction. Theoretically, one or the other mechanism might be the determining factor in different cases.

Such clinical concepts find some confirmation in experimental work on animals. Porter² and Maass³ demonstrated a vasomotor control of the coronary flow. This work has been confirmed and extended by Anrep,⁴ Greene,⁵ Rein¹ and others. Reflex changes in coronary flow have been demonstrated by these same authors. That such changes in coronary flow may result clinically from factors occurring in daily life is evidenced by the coronary vasoconstriction which Anrep,⁴ Greene⁵ and others have shown to result from an increase of cephalic blood pressure past a certain point. In the cases reported by Lewis⁷ in which anginal attacks occurred after a rise in pressure past a certain point, it seems probable that some such mechanism was present. The effect of gaseous distention or hiatus hernia in provoking attacks has long been a common observation. Von Bergmann⁸ has shown that the inflation of a balloon in the stomach of the dog produced a coronary vasoconstriction abolished by atropine or vagus section. Fenn, LeRoy and I have confirmed this work in the last few months and will report on it later.

Hall⁹ and de Takats and Fenn¹⁰ have recently reported on reflex vasomotor changes in the coronary arteries following coronary occlusion and following pulmonary emboli.

It seems probable also that there is such a thing as toxic vasoconstriction, as Huchard predicated, resulting either from a direct effect on the vasomotor mechanism or reflexly from other visceral effects of the agent. That some drugs have a vasoconstrictor effect is known, and considerable evidence is accumulating against tobacco.

The assumption of vasomotor changes in the caliber of the coronary arteries is not new, dating well back into the last century. Such reflex vasomotor response or lack of response is not a normal physiologic process and is not to the advantage of the organism. In that respect it is not unique, sharing a place with esophageal or gastric neuromuscular disturbances, spastic colon, bronchial asthma and allied symptomatic disorders. It is necessary to predicate some alteration in the normal physiologic background which renders nerves and tissues more amenable to subversive propaganda. Deviations from the physiologic normal involving hyperactivity or hypoactivity of the autonomic nervous system are matters of daily observation in clinical practice. They are the basis of many of the disorders on which the physician is called to give advice.

If one assumes that the lack of equilibrium between the needs of the heart muscle and the blood supply can result from vasomotor changes or from lack of such changes, as well as from anatomic changes, one will explain a great many of the observations regarding not only angina pectoris but degenerative changes in the heart muscle which it is difficult to explain on a purely structural basis.

It is recognized, for example, that angina pectoris frequently occurs in patients of whom there is no clinical reason to suspect pathologic changes in the heart or its vessels and in whom there is no clinical or laboratory evidence of such changes. At autopsy such persons frequently show only such alterations as would be expected at the age at which they die. It must always be borne in mind that most persons will have very definite coronary changes by the age of 45, as shown by Brooks.¹¹ Also, as Allbutt puts it, "few elderly persons die without as much coronary disease as would content a coronarian disputant," and yet only a portion will have had angina.

The assumption of a vasomotor factor would also explain why angina seems to be more frequent in a group of persons who appear to be more highly organized or less stable nervously or who have what Houston¹² referred to as the "spasmogenic aptitude." In such a group, autonomic imbalance is frequently expressed in many ways.

In this connection the observations of Gregg¹³ are of interest. In a study of a psychotic group as compared with the normal population, he found coronary disease one-fourteenth as frequent and ulcer of the stomach one-third as frequent in the psychotic group. He stated the belief that this is because in the normal

person there is a more prolonged physiologic response to autonomic stimuli, while in the more primitive pattern of the psychotic person such reactions are brief and the organism is relatively immune to the results of emotional stress and fatigue. It is possible also that emotional phenomena express themselves in behavioristic activity rather than in a physiologic equivalent.

The assumption of such vasomotor phenomena would also explain the frequent occurrence of angina pectoris in patients working tensely, under conditions of stress and strain, with inadequate rest and relaxation. There is reason to think that fatigue and emotional stress also tend to produce an autonomic imbalance, just as during the World War the aviators showed evidence of an overlabile autonomic system as the result of staleness. This condition would be relieved by a period in the rest camp.

It would also explain why the patient who suffers daily attacks of angina of effort under the strain of his daily work is able to undergo much more physical effort without attacks while he is away on vacation. On his return to what Dr. Bucknill, in his reply to Thomas Arnold, referred to as the "anxiety and eager competition" of his business life, he experiences the return of the attacks. Certainly the anatomic condition of the coronary arteries does not change back and forth between city and country.

It would explain also the occurrence of anginal pain in the so-called effort syndrome, or neurocirculatory asthenia. Whatever the group with this condition may or may not be, it is a group of younger persons characterized by an overlabile autonomic system, responding to smaller stimuli than normal and over-responding to such stimuli. This condition frequently follows as the result of fatigue or of physical or psychic trauma. It may follow such trauma in normal persons, if the trauma is severe enough or exerted over a long enough period. It will result more readily in the group which Campbell¹⁴ classified as "constitutionally inferior."

It is my own impression also that such an assumption of a vasomotor factor might explain in part the age incidence of angina. Several years ago I attempted to show that the autonomic response as measured by digital pressure on the carotid sinus increased with age up to the middle or late fifties and then showed a decrease, with a curve approximating the morbidity curve of angina pectoris.¹⁵

Quite apart from angina pectoris, however, I think that one should bear in mind the possible results of such frequently repeated vasomotor changes on the structure of the cardiac muscle and their part in heart failure.

Hall, Ettinger, Banting and Manning¹⁶ have shown the anatomic changes produced in the heart muscle of the dog by a prolonged or repeated vagus stimulation. Blumgart and his co-workers¹⁷ have shown that temporary arrest of the blood flow in a single coronary artery leads to anoxic electrocardiographic changes

in one minute. Arrest of flow for from twenty-five to forty-five minutes resulted in areas of necrosis.

As I have said previously, the assumption of such vasomotor influences on the coronary flow is by no means new and is a clinical concept accepted in whole or in part by a large number of clinicians today. In attempting to emphasize its importance, I do not wish to appear to minimize at all the importance of anatomic changes. The physiologic factors are frequently superimposed on such anatomic changes. Nor do I wish to minimize the importance of the many other factors of which the volume of coronary flow is the resultant. Among these are included the observations of Dr. Kerr,¹⁸ confirmed as they are by his therapeutic results, and the work of Kountz¹⁹ and others.

Such vasomotor phenomena constitute only one factor in many. The primary importance of such physiologic factors lies in the place which they hold in therapy and in future lines of investigation. Dr. J. B. Murphy used to say: "Listen to the patient's story. He is telling you the diagnosis." And, one might also add, the patient is giving you hints as to treatment. The necessity of avoiding any stimuli which might tend to produce any vasomotor changes in the coronary blood supply is obvious. There is also the possibility of avoiding or minimizing such stimuli by therapy directed toward that end. Because of the nervous background in so many cases, what Kipling once referred to as "the therapeutic value of words" is often quite as important as any one form of therapy.

Because a patient has typical anginal pain does not always mean that conditions are present in the heart which absolutely preclude any possibility of an adequate coronary flow. Changes in the coronary arteries are undoubtedly present in the usual case of angina pectoris, just as such changes are present also in any normal person of a similar age. In many cases the anatomic changes in the coronary arteries are the largest single factor, or even the one single factor, responsible for the symptoms. In a great many others, such arterial changes are only one of many anatomic and physiologic factors. Just what these other factors are must be sought for in the patient's history and in the physical and laboratory examinations.

Treatment must depend on an evaluation of just what conditions are valent in producing a disproportion between cardiac needs and cardiac blood supply. In spite of all that has been said and written, a great deal still remains to be learned with regard to the physiologic background of anginal pain and with regard to therapeutic means to offset or combat whatever conditions may be responsible for angina pectoris.

Ideal Weight.—The amount of fat which an individual should normally carry can only be stated vaguely. The ideal quantity is undoubtedly that which allows the maximum of physical enjoyment and mental happiness. Every one should be acquainted with the weight which is best for himself, remembering the figure in stones and pounds just as readily as he remembers his size in hats, gloves, shoes and stockings. For most people the best weight is that which they held in the twenties, but as age advances many leave it gradually behind; most people look back to those years as the fittest of their existence.—Christie, W. F.: *Ideal Weight: A Practical Handbook for Patients*, London, William Heinemann, 1938.

POLYPS OF THE COLON AND RECTUM AND THEIR RELATION TO MALIGNANCY

NEIL W. SWINTON, M.D.

AND

SHIELDS WARREN, M.D.

BOSTON

During the past ten years the treatment of carcinoma of the colon and rectum has been vastly improved. At this clinic the resectability of lesions of this type has risen from 50 per cent in 1928 to 89.9 per cent for the year 1938. In the same period the operative mortality has also been greatly reduced. A mortality of 36 per cent in 1928 has been lowered to 10 per cent in 1938. These figures are but an index of what has occurred generally when there has been an especial interest in this subject. The improvements have been due largely to the better preparation of these patients for operation, improved anesthesia, increased experience in the actual removal of these lesions and better post-operative care. The end results following the removal of malignant lesions of the colon and rectum are among the most satisfactory of any group of patients with malignant disease. In this clinic at the present time 42 per cent of the patients who have undergone radical resection for carcinoma of the colon and 47 per cent of those who have undergone radical operation for carcinoma of the rectum are alive and well, without evidence of recurrence, five years after operation. However, last year, in reviewing a series of 300 patients with carcinoma of the colon and rectum, we were a little discouraged to find that the average duration of symptoms at the time of resection was nine months. This was the same duration that was revealed by a similar study five years previously. We believe that the early diagnosis of malignant disease in the large bowel has not been sufficiently emphasized and that there is a need for further study and discussion of the development and early stages of carcinoma of the colon and rectum.

It is our purpose in this paper to review a series of 156 patients with benign and malignant polyps of the colon and rectum who have been operated on at this clinic during the past eight years. By this study we hope to bring about a more widespread understanding of the development of malignant disease in this region and emphasize factors that will bring these patients to operation earlier than in the past.

In this analysis of polypoid disease of the large bowel the premalignant nature of polyps of the colon and rectum will become evident. The etiology of this disease will be briefly discussed. The transition of benign polyps into carcinoma will be reviewed from a clinical and histologic standpoint. Criteria will be discussed for the diagnosis of malignancy in polypoid disease of the large bowel. The plan of management in both the study and the treatment of these patients as employed in this clinic will be presented.

The term polyp has been defined as a tumor arising from mucous membrane and attached to that mucous membrane by a pedicle. In this study the term polyp will include not only those pedunculated tumors arising

from the wall of the large bowel but also those sessile tumors arising from mucous membrane which have no demonstrable pedicle. We refer to these polyps as mucosal polyps; the majority are true adenomatous polyps, although in a few fibromatous and papillomatous characteristics may predominate. Thrombosed internal hemorrhoids, hypertrophied anal papillae and other

Fig. 1.—Benign mucosal polyps of the rectum seen through the sigmoidoscope.

fibrous tumors arising distal to the true rectal mucosal segment have been erroneously referred to as rectal polyps. We have never seen malignant disease develop in tumors of this type, and such polyps are not included in this study.

Polyps of the colon and rectum may be single or multiple and may be found in any portion of the large bowel. They may involve the entire colon and rectum. Clinically, we classify mucosal polyps as benign or malignant, single or multiple, and refer to cases of multiple polyps as multiple polyposis. Buie¹ has pointed out that this use of the term multiple polyposis is fundamentally incorrect; nevertheless it has been

Fig. 2.—Benign polyp in sigmoid demonstrated by contrast air enema technic.

generally accepted. The cases of polypoid disease of the entire colon and rectum, demonstrated by McKenney² to be congenital in character, we refer to as congenital multiple polyposis of the colon and rectum.

2. McKenney, D. C.: *Multiple Polyposis of Colon: Familial Factor and Malignant Tendency*, *J. A. M. A.* 107: 1871-1876 (Dec. 5) 1936.

Histologically, the structure of polyps varies markedly. A fairly typical polyp may be described as an epithelium covered stalk of connective tissue, moderately vascularized and usually provided with a muscularis mucosae continuous with that of the intestinal wall, and it may contain scattered smooth muscle fibers in its deeper substance. This stalk may be single and fairly straight or it may be frondlike. Multiple closely adjacent stalks may make up a single sessile polyp. The covering epithelium ranges from the normal mucosa of the large intestine to irregular glands, variable in size and shape and lined with tall columnar epithelium with large, vesicular nuclei and prominent nucleoli frequently containing mitotic figures. Many times the normal mucosa is absent or is present only along the base of the stalk. The amount of mucous secretion varies greatly; goblet cells may be numerous. Masses of mucus may occur on the surface of the polyp and may penetrate into its stroma. Occasionally no mucous secretion is apparent.

Fig. 3.—Malignant adenoma of transverse colon.

In the sessile type of polyp with broad base there may be multiple small prolongations of the submucosa of the intestine with any of the aforementioned types of mucosa covering them. In these the strands of connective tissue are never so long as in the more common type and the amount of muscularis mucosae varies greatly, sometimes being entirely absent. In all polyps the mucosa is of fairly even thickness and usually shows well defined boundaries from the stroma.

In either type of polyp there is usually no evidence of inflammatory reaction other than a slight lymphocytic infiltration at the base. Rarely focal ulceration or necrosis may be present, usually at the tip. Owing to the marked vascularity, small hemorrhages may occur and hemosiderin-laden macrophages appear in the stroma as evidence of past trauma. The mucosa of the polyp always merges smoothly with that of the adjacent normal intestinal wall and frequently it will be noted the normal mucosa continues well out along the stalk.

It is possible in our series to demonstrate histologically all stages in the sequence of change from normal colonic mucosa to actual adenocarcinoma.

The etiology of polyps of the colon and rectum has not been accurately established. McKenney has made a careful study of a group of patients with polyps, one of whom was an infant aged 2 years. He obtained convincing evidence of the congenital nature of the cases of multiple polyposis of the entire colon. Erdmann and Morris³ classified all cases as either congenital or acquired. The reported frequent observation of the development of multiple polypoid-like structures in cases of ulcerative colitis suggests the "acquired" nature of some of these tumors. From a microscopic study of a large series of intestines from patients with chronic ulcerative colitis, both specimens removed surgically at varying lengths of time after onset of the disease and specimens obtained at autopsy, we believe that chronic ulcerative colitis is not a factor predisposing to the development of polyps. While the very extensive ulcerations may at times fuse and leave elevated strips of mucosa, or may actually undermine strips of mucosa communicating with one another so that bridges or free tags of mucosa may be left, examination of these bridges or tags which may simulate polyps shows a definitely different type of structure. The mucosa is

Fig. 4.—Large benign mucosal polyps successfully removed from sigmoid by colotomy.

never normal, nor is there the usual hyperplastic change seen in polyps. Instead, there are atrophy of the mucosa and varying amounts of chronic inflammatory reaction, often with fibrosis—a marked contradistinction to the neoplastic type of polyp.

In our patients with ulcerative colitis we have observed another interesting fact. Following healing of the acute ulcerative process, we have known these pseudopolypoid tumors to regress and disappear. After ileostomy and total colectomy in multiple stages in patients with severe ulcerative colitis in which tumors of this type have developed, examination of the removed sections of colon and rectum has frequently revealed the complete disappearance of these mucosal irregularities. We have never observed the regression or disappearance of true polyps of the large bowel except in rare instances in which the polyp has broken away from its pedicle. This, of course, also definitely suggests that the pseudopolypoid tumors resulting from known irritation and infection have different fundamental growth characteristics than the discrete and multiple polyps which are not the result of known infectious processes. It must be recognized that, in cases of extensive polypoid disease of the large bowel, bleeding and discharges will frequently be observed. The marked

3. Erdmann, J. F., and Morris, J. H.: Polyposis of the Colon, Surg., Gynec. & Obst. 40: 460-468 (April) 1925.

increase in epithelial surface and the increased activity of the mucosa of the polyp account for the increased mucus in the stool. The numerous thin-walled vessels in the stalk are easily traumatized and are the source of frequent small hemorrhages. The differentiation between ulcerative colitis in which polypoid changes

Fig. 5.—Malignant adenoma originating from mucosal polyp removed by modified Mikulicz resection.

have taken place in the mucous membrane and multiple polyposis associated with blood and increased amounts of mucus in the stool must be recognized. We have never observed the polypoid changes seen in ulcerative colitis progress to a malignant stage.

Because of these facts and because of the well demonstrated congenital nature of the cases of multiple polyposis of the entire large bowel, we believe that the majority of polyps of the large bowel are true tumors and are the result of some inherent defect in cellular growth.

Fig. 6.—Adenocarcinoma of the colon arising in benign mucosal polyps removed by modified Mikulicz resection.

There is no way in our series of cases of polypoid disease to determine the true incidence of colonic and rectal polyps. Buie has reported that about one in thirty-five patients on whom proctoscopy was performed for colonic and rectal disorders had polyps. Lawrence,⁴

4. Lawrence, J. C.: Gastrointestinal Polypos, Am. J. Surg. 31: 499-505 (March) 1936.

reporting a series of 7,000 autopsies from the Cook County Hospital, found an incidence of polyps in the colon of 2.37 per cent and in the rectum of only 0.42 per cent. Lawrence quotes Susman as finding an incidence of polyps in the colon of 6 per cent in a series

Fig. 7.—Section of benign mucosal polyp of pedunculated type. Note normal mucosa on one side of stalk and abnormal mucosa on other; reduced from a photomicrograph with a magnification of 8 diameters.

of 1,100 autopsies. This low incidence of polypoid disease in the rectum as compared with that in the colon does not agree with our experience, as our figures

Fig. 8.—Mucosal polyp of sessile type. Note multiple prolongations of the submucosa of the intestine.

will demonstrate. As our interest in polypoid disease of the colon and rectum has increased and our indications for proctoscopic and roentgenographic examinations have widened, we have found more and more polyps in this region, and we believe that the incidence of polyps of the rectum and colon is much greater than has been recognized.

The location of the polyps found in this series of patients is identical with the generally recognized distribution of carcinoma in the colon and rectum. Seventy per cent of the polyps in this series were visualized through the 10 inch sigmoidoscope. In this study we have included only those cases in which histologic sections were made of the removed polyps. There have been an additional number of instances of polyps that were small and were destroyed by fulguration in which no sections were taken for microscopic examination. Actually the incidence of polypoid disease in our series that could be demonstrated on sigmoidoscopic examination was above 70 per cent.

In thirty-five cases in this series the polyps were benign. Single polyps were found in thirty-one and multiple polyps in four. Malignant polyps were encountered in 121 cases. A malignant adenoma alone was found in seventy-two cases and multiple malignant adenomas were noted in four other cases. The malignant adenomas were associated with either single or multiple benign polyps in forty-two additional cases. Three cases presented the congenital type of multiple polyposis, in two of which malignancy was present at the time of resection.

Fig. 9.—Adenocarcinoma arising in the tip of a benign mucosal polyp. Insert shows cross section of the entire polyp with its base and adjacent intestinal mucosa.

This high incidence of multiple polypoid lesions, both benign and malignant, must be recognized and emphasized. In this series of 156 patients the polypoid lesions were multiple in 35 per cent.

Polypoid disease may be found at any age. The patients with benign polyps in our series varied in age from 7 to 80 years. The average age was 53. In the malignant group the average was 57.7 years. The youngest patient with a malignant adenoma was 13 years of age and the oldest was a man of 76. We do not see a large number of children in this clinic and we do not believe that we have a representative age group to determine accurately the age incidence of polypoid disease in younger persons.

The proportion of males and females with either benign or malignant polyps was equal.

Unfortunately, polyps do not give rise to symptoms early in their development. Bleeding was associated with one half of the benign polyps in our series, and in the majority of these cases it would be difficult to determine whether the bleeding came from the polyps or from associated anal disease. Brust⁵ stated that in

5. Brust, J. C. M.: Solitary Adenomas of the Rectum and Lower Portion of the Sigmoid, Proc. Staff Meet., Mayo Clin. 9: 625-631 (Oct. 17) 1934.

his series the symptoms were referable to the polyp in only 20 per cent of the cases. In our series 76 per cent of the polyps were less than 1 cm. in diameter. It is inconceivable that small, discrete polyps of the large bowel frequently give rise to symptoms. As

orders of any type. Particularly is this important with patients giving a history of any abnormality of their stools or alteration in their normal bowel function. The fact that 70 per cent of all polypoid disease in the colon and rectum and 68 per cent of all malignant lesions in this region can be visualized with the 10 inch sigmoidoscope makes this type of examination in these patients imperative.

Roentgenographic studies of the colon should be carried out when the source of rectal bleeding is not obvious from sigmoidoscopic examination and likewise when nonobstructing lesions of any type are seen in the rectum or rectosigmoid regions, in order to determine the multiplicity of these lesions. Studies after administration of a barium enema must always be carried out when there is a history of altered bowel function or unexplained abdominal pain or when an unexplained abdominal mass can be palpated.

In the roentgenographic study of the colon for benign polyps and early malignant lesions, preparation of the colon is essential. At this clinic we give these patients 1 ounce (30 cc.) of castor oil the night before roentgenograms are taken and cleansing enemas the morning of such examinations. It is also necessary in localizing small organic lesions in the colon to employ the contrast air technic in addition to the usual barium enema studies.

When a polyp of the rectum or colon has been visualized, its benign or malignant nature must be established. One of the most important facts that we have learned from our experience with this group of tumors has

Fig. 10.—Malignant adenoma arising from benign mucosal polyp; reduced from a photomicrograph with a magnification of 250 diameters.

these polyps become larger, however, the incidence of bleeding, mucus and, in rare instances, obstructive symptoms will be more frequent. Likewise the more extensive the involvement of the colon and rectum with polypoid disease, the greater the glandular development and the higher the incidence of bleeding and mucous discharges. The three patients with congenital multiple polyposis included in this group were 19, 33 and 39 years of age; in two of these, malignant degen-

Abdominal cramps or pain.....	7	77	87	57
None.....	2	2	3	2.3

eration had taken place at the time of operation. These patients all presented symptoms of bleeding, discharge, abdominal cramps and pain, and two had severe anemia.

A review of the malignant polyps in this series shows that the symptomatology does not differ from that of the other types of malignant disease found in the large bowel. In the accompanying table are shown the symptoms presented by a group of 100 patients with carcinoma of the rectum, 100 with carcinoma of the left colon and 100 with carcinoma of the right colon, taken at random from our files. The importance of rectal bleeding, altered bowel function and the presence of unexplained abdominal pain in the early diagnosis of malignant disease can be seen from this table.

At this clinic it is our policy to do sigmoidoscopic examinations on all patients with rectal and colon dis-

Fig. 11.—Normal mucosa contrasted with adenocarcinoma; reduced from a photomicrograph with a magnification of 250 diameters.

been that the preoperative diagnosis of malignancy in polypoid disease of the colon and rectum will not always be accurate if too much dependence is placed on the pathologist's report of the biopsy specimen. Microscopically, it is relatively difficult to determine the presence or absence of malignant change in intestinal polyps. While the fully developed carcinoma is easily

recognized by the anaplastic character of the cells, the irregularity of the glandular structure and the invasion of not only the immediate stroma but also the adjacent intestinal wall, there are many early or transitional forms that are difficult to classify. If one accepts three important criteria of malignancy—anaplasia, irregularity of architecture, and invasion—it is necessary to have at least two of these three factors present before making a diagnosis of malignant growth. It is possible for any one of these three criteria to be present without an actual malignant condition, with one exception: Definite lymphatic or intravascular invasion nearly always means a clinical malignant condition.

It is important, in attempting a histologic diagnosis, to recognize that different portions of the polyp may present entirely different histologic pictures. Therefore we feel that it is important to make a sufficient number of representative sections and to include an adequate representation of the base. It is particularly important to determine whether or not the base is

or malignant nature. Ulceration, nodular irregularities and a broad pedicle and base suggest malignant change. Firmness, induration and fixation to palpation are pathognomonic of malignant disease. Although it is probably true that a malignant condition is rare in polyps less than 1 cm. in diameter, during the past two years we have encountered malignant change four times in polyps smaller than a walnut. The size of a polyp is not an accurate index of its benign or malignant character.

In the last eight years we have operated on 82 patients with malignant tumors of the colon and rectum. In 32 per cent of this series the lesions were in the colon, and in 68 per cent the malignant condition was found in the rectum and rectosigmoid region of the colon. In 120 cases, or 14 per cent of this entire series, the lesions were true malignant adenomas. We believe that we can say from our study of this series of cases that 14 per cent of the malignant tumors of the colon and rectum can histologically be demonstrated to have

Fig. 12.—Method of fulguration of broad, sessile polyp and removal of pedunculated polyps with high frequency electric snare. The Buie type sigmoidoscope with built in suction is very useful for this work.

arisen in benign mucosal polyps. In the remaining cases of carcinoma of the colon and rectum the invading tumor was so extensive that the original architecture of the tumor could not be identified, but we believe that a much larger percentage of carcinoma of the colon and rectum arises from preexisting benign mucosal polyps. Fitzgibbon and Rankin,⁷ following the classification of Schmieden and Westhues,⁸ believe that certain polyps never undergo malignant degeneration. Although polyps that are entirely covered with normal mucous membrane may not become malignant, clinically we believe that this is a dangerous doctrine to follow. The facts that in 14 per cent of all our cases of carcinoma of the colon and rectum the malignant condition can be demonstrated to have arisen from mucosal polyps, that in our series it has been possible histologically

to demonstrate all stages in the sequence of change from normal mucosa to adenocarcinoma and that the distribution of polypoid disease in the colon and rectum parallels the distribution of malignant growths in this region are sufficient evidence to justify consideration of all polyps of the colon and rectum as pre-malignant lesions.

We believe that malignant change may begin anywhere in a polyp. Saint⁶ has pointed out that the youngest glands will always be found near the periphery of a polyp and that early malignant change in a polyp will be found near its tip. This cannot be depended on in determining malignancy in polypoid disease. In a patient recently examined, we removed fourteen sections of tissue from a large polyp before finding a region of malignant growth in the polyp near its base. The entire polyp together with its base must be examined microscopically for an accurate diagnosis of malignancy. However, in a few of the broad based polyps complete removal may not be feasible. In tumors of this type biopsy specimens should be taken from the firmest areas near the base of the polyp.

The visualization and palpation of polypoid structures are of the utmost importance in establishing their benign

7. Fitzgibbon, Grattan, and Rankin, F. W.: Polyps of the Large Intestine, *Surg., Gynec. & Obst.* 52: 1136-1150 (June) 1931.
8. Schmieden, V., and Westhues, H.: Zur Klinik und Pathologie der Dickdarmpolypen und deren klinische und pathologisch-anatomischen Beziehungen zum Dickdarmkarzinom, *Deutsche Ztschr. f. Chir.* 202: 1-124, 1927.

6. Saint, J. H.: Polypi of the Intestine with Special Reference to the Adenomata, *Brit. J. Surg.* 15: 99-119 (July) 1927.

polyp has been removed at frequent intervals for a period of months to be certain that the tumor does not recur. In polyps above the reflection of the peritoneum and in the rectosigmoid region of the colon, considerable care must be exercised to avoid perforation of the bowel. Troublesome hemorrhage may at times be encountered. We have never had to proceed with resection to control hemorrhage following fulguration, but particularly in polyps that lie at a high level this possibility must be borne in mind. The removal of large polyps and all polyps that arise above the peritoneal reflection should be carried out in a hospital where all facilities are available.

CONCLUSIONS

From this review of 156 patients with polypoid disease of the colon and rectum the following conclusions may be drawn:

1. Polyps in this region are not the result of diffuse inflammatory processes but are true tumors.
2. The incidence of polypoid disease in the colon and rectum is not known, but we believe that it is much more common than has been recognized.
3. Seventy per cent of the polyps in our series could be visualized through the 10 inch sigmoidoscope, but they may be found anywhere in the colon or rectum. This distribution is the same as that of malignant growths found in this region.
4. Thirty-five per cent of the patients in this series had multiple polyps.
5. Polyps may occur at any age and have an even distribution in the sexes.
6. Symptoms due to early benign polyps are rare. Symptoms due to malignant polyps are primarily an alteration in the stool, the presence of blood or mucus, an alteration in bowel function and abdominal pain.
7. The detection of polyps of the colon and rectum depends on sigmoidoscopic and roentgenographic studies. The importance of the preparation of patients for these examinations and the use of the contrast air enema must be appreciated.
8. Histologically, in this series all stages in the sequence of change from normal mucosa to adenocarcinoma can be demonstrated.
9. In the determination of malignancy in polypoid disease the importance of the inspection and palpation of these tumors is emphasized. Histologically, the diagnosis of malignant change depends on the study of the entire polyp together with its base.
10. In our series of 827 patients with carcinoma of the colon and rectum, 14 per cent can histologically be demonstrated to have arisen in benign mucosal polyps. We believe that a high percentage of malignant change in the colon and rectum arises in previously benign polypoid tumors.
11. From the data presented in this analysis we believe that polyps of the colon and rectum are true tumors which are premalignant lesions; that polyps in this area are much more common than has been appreciated and that if all physicians called on to treat disorders of any type of the colon or rectum will submit these patients to sigmoidoscopic and roentgenographic studies an increasing number of polyps will be found, the incidence of carcinoma of the colon and rectum will be reduced and patients with malignant lesions will be submitted to operation earlier than has been the case in the past.

THE ADVANTAGE OF PERINEAL OVER ABDOMINAL COLOSTOMY

WITH TECHNIC FOR TRANSFERRING THE ABDOMINAL OPENING TO THE PERINEUM

W. WAYNE BABCOCK, M.D.

PHILADELPHIA

In 1930, having observed marked advantages of a perineal colostomy in resections of the pelvic colon, I eliminated a permanent abdominal opening in any case in which the lesion was considered surgically removable. Since this change in technic 220 patients with cancer of the large intestine have been treated by operation. In twenty-six instances the disease was so advanced that only an exploration or colostomy was done. In 103 the rectosigmoid was resected with the formation of a perineal anus but without sphincter control. After the first three or four months of adjustment these patients have been very appreciative of the perineal opening, quite different from the attitude of many who have been left with an abdominal colostomy. An abdominal colostomy necessitates a pad or other protection. With an adequate perineal opening, although without sphincter control, 5 per cent of my patients require no local protection, special diet or other measure to prevent soiling; 50 per cent by regulated emptying of the colon and some restriction in diet are enabled to dispense with a pad much or all of the time; 30 per cent find the constant wearing of a pad desirable although it is infrequently soiled, while 15 per cent, chiefly those careless as to diet and personal hygiene and those with local recurrence, report frequent soiling.

But the person best able to evaluate the perineal as contrasted with the abdominal colostomy is the man who has had both. Such evidence is presented by four patients for whom I have moved an abdominal colostomy to the perineum. The abdominal colostomy had been present for from seven months to eleven years and in three instances it was well formed and uncomplicated.

CASE 1.—Dr. H. S., aged 47, in September 1936 had a one stage abdominoperineal proctosigmoidectomy for carcinoma. A well formed median abdominal colostomy resulted; evacuations were controlled by colonic irrigations every eight hours.

Nov. 27, 1937, transplantation was made of the colostomy with an attached ring of abdominal skin to a sphincterless perineum. The patient was ambulant and discharged from the hospital ten days later.

March 1939 he reported a gain of more than 15 pounds (6.8 Kg.), no incontinence, escape of gas only once or twice daily, and ability to use a more varied diet than with the abdominal colostomy. The colon is emptied every other morning by a plain or salt water enema, between which times he is free from soiling.

CASE 2.—Miss M. H., aged 58, had been treated for mucous colitis with diarrhea for eighteen months when vaginal bleeding from invasion of a rectal carcinoma developed.

April 21, 1938, a one stage abdominoperineal proctosigmoidectomy, panhysterectomy, vaginal resection and left inguinal colostomy were done. Small cancerous nodules were palpated in the liver.

By October 27 she had lost her cachectic appearance and had gained 8½ pounds (3.8 Kg.) but had had to give up her work in a bank because of offensive gaseous discharges from the colostomy.

Read before the Section on Gastro-Enterology and Proctology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

November 3 the colostomy was moved to the sphincterless perineum. The nodules in the liver had enlarged.

November 13 she was out of bed; the colostomy was nearly healed.

December 1 she reported that each enema is followed by freedom from movement for three days. There is much less discharge of gas, better control and warning and less care and more comfort than with the abdominal colostomy.

In April 1939 there was increasing weakness with enlarging liver.

CASE 3.—Mrs. F. H., aged 32, weighing 90 pounds (40.8 Kg.), had had increasing diarrhea for two years with occasional blood spotting, recurrent abdominal cramps for six months and rectal distress for four weeks. The diagnosis was cancer of the proctosigmoid, infiltrating the uterus, upper part of the vagina and the region of the right ureter.

March 31, 1938, a one stage abdominoperineal proctosigmoidectomy, panhysterectomy, partial colectomy, resection and anastomosis of the right ureter, incision of the bladder and left inguinal colostomy were done. Postoperative herniation of the ileum into an open drainage tube and secondary ileal, ureteral and vesical fistulas occurred.

Fig. 1.—(a) The sump drain is valuable in the prevention of spreading peritonitis by keeping the peritoneal cavity free from blood, serum and contaminating fluids during and after the operation. Aspiration, most conveniently produced by a miniature electric pump and collection bottle, should be continuous for the two or three days after operation, that the general peritoneal cavity may be drained by glass. These tubes, of any desired diameter, length or curve, may be made by any glass blower. (b) Glass lamp chimney drain, to be anchored by four alloy steel wire sutures over intestinal suture lines or septic or necrotic areas. These glass tubes, from 2 to 6 cm. in diameter, enable the daily inspection of questionable healing processes within the body and provide a large vent for fecal and other drainage. Differing from gauze and rubber drains, the glass is not walled off by adhesions for several days. These drains should not be used unless they are so anchored that viscera will not enter and herniate.

In July 1938 abdominal closure of ileoperineal fistula was done.

Jan. 27, 1939, transplantation of the abdominal colostomy to the perineum was done, with closure of the vesical fistula and a secondary temporary ileostomy.

April 2 a right nephrectomy was done for the uteroperineal fistula.

April 13 she weighed 105 pounds (47.6 Kg.). She was in excellent condition. Evacuations were produced only by enema every third day. There was no evidence of recurrence. There was a marked improvement over the abdominal colostomy.

CASE 4.—S. B., a man aged 60, had a two stage proctosigmoidectomy for carcinoma with a left inguinal double barreled colostomy in 1927, followed by an incisional hernia and massive eventration of the proximal and distal loops through the colostomy opening. The colostomy required hours of attention daily. There were recurrent draining sinuses in the perineal scar for which six or more operations had been done. Pollakiuria and nycturia were present for two years following irradiation.

Dec. 5, 1938, the abdominal colostomy was transferred to the sphincterless perineum with excision of redundant bowel and distal loop. Repair of the incisional hernia was accomplished with buried alloy steel wire sutures. The adherent bladder in the perineal scar was entered and sutured.

April 1939 the condition is much improved. There are bowel movements only with enemas, without interval soiling. Pollakiuria is decreasing.

These four patients offer impressive evidence of the superiority of the perineal outlet. It is less messy and more convenient to care for. It requires little or no local protection. Fecal discharges are infrequent and occur with better warning and the expulsive effort of the abdominal muscles is more effective. Escaping flatus is not as obvious and apparently is better controlled, the pressure of the buttocks being an added restraining factor.

The perineal opening also enables the early detection of a pelvic recurrence by palpation. Thus in six cases a recurrent nodule was detected and excised at a relatively early stage. Three of these patients are now living without palpable recurrence from two to more than four years after the last operation. Without the diagnostic advantage of the perineal opening, such recurrences may reach an inoperable stage before detection.

The site of the colostomy may influence marriage, as in the case of the woman of 32 who insisted that the abdominal opening be moved to the perineum. A second patient after an abdominoperineal proctosigmoidectomy with perineal opening at 27 has married and is considering pregnancy at the age of 31.

As with an abdominal colostomy, the comfort of the patient with the perineal opening depends largely on determining and utilizing the storage function of the colon. If the patient regularly empties the colon just before its capacity has been reached he will, as a rule, have freedom from evacuation for from twenty-four to seventy-two hours. Most patients obtain the best results from a physiologic solution of sodium chloride or tap water enema

taken in the morning or evening every twenty-four to seventy-two hours. For the seventy-two hour schedule a low residue diet the day after the enema followed by a full diet the day preceding the enema often works well. About 20 per cent of the patients, however, prefer a small dose of a quickly acting saline laxative, such as one or two teaspoonfuls of sodium sulfate taken in a little cold water immediately on arising. Soon after breakfast, which includes a cup of hot coffee, the colon empties, after which constipation follows for the two or three days it is found feasible to wait before repeating the laxative. A few of the patients prefer the action of a small amount of castor oil, which with them leaves a more secure secondary constipation. Of course, liquid petrolatum or laxatives of delayed or prolonged action should not be used. In any case the perineal orifice should be of adequate size. A narrow or stricture!

PERINEAL COLOSTOMY—BABCOCK

1935

outlet prevents the rapid and complete emptying of the colon, and consequently small, frequent and annoying discharges from overflow result. This should be overcome by dilation, the patient daily inserting test tubes or other dilators. A redundancy or protrusion of the mucosa of the sigmoid may cause an unpleasant local moistness, easily corrected without anesthesia by linear galvanocauterization or the injection of a 5 per cent solution of quinine and urethane. A perineal hernia is apparently less common than the hernia often seen about an abdominal colostomy. In two of my cases, however, I have operated for such a perineal protrusion.

TECHNIC

In the formation of a perineal colostomy the method described in 1932¹ has been used with modifications. Since the bowel may be accidentally entered during the operation, the rectum should be cleansed by thorough irrigation and packed with three or four gauze sponges wet with one half strength tincture of iodine or with tincture of mercury bichloride immediately before the operation. A 14 F. soft rubber catheter should be fastened in the bladder to be removed after forty-eight hours.

Spinal anesthesia from an intradural injection of 10 mg. of pontocaine hydrochloride mixed with 50 mg. of procaine hydrochloride is favored on account of its prolonged action. Usually this is followed by from 100 to 250 cc. of a 1 per cent epinephrinized procaine solution, injected locally. During the operation, if the patient is asthenic, from 500 to 1,000 cc. of 5 per cent dextrose, possibly followed by typed citrated blood, is slowly run into a vein.

For the patient in very poor physical condition, the following method of anesthesia has been found of advantage: A slow intravenous infusion of 5 per cent dextrose is started and continued during the operation. As the patient slowly counts, a 2.5 to 5 per cent solution of evipal soluble is injected through the rubber tube close to the intravenous needle, at the rate of about 1 cc. every ten seconds. When the patient stops counting, the evipal soluble is discontinued, the abdominal incision is quickly made and the abdominal wall and subperitoneal layers are freely infiltrated with a 1 per cent solution of procaine hydrochloride containing 1 minim (0.065 cc.) of epinephrine to each 10 cc. With a pump syringe and a 20 or 22 gage needle from 250 to 500 cc. of the solution is injected. With this combination little additional amounts of evipal soluble may be required so that the patient may doze through an operation lasting an hour and a half from a total of only 0.6 or 0.8 Gm. of evipal soluble. If indicated, carefully typed citrated blood follows the infusion of dextrose. With these methods of anesthesia it is not uncommon to find the patient in better condition at the end than at the beginning of an extensive operation, and in no case as sufficient shock occurred to prevent the completion of a radical one stage operation.

In recent years most of my operations on the colon have been made through nearly transverse incisions of the muscle splitting, rectus retracting type. These incisions reduce the exposure and possible contamination of the general abdominal cavity and leave a stronger and better scar than vertical incisions. They are especially adapted for the exteriorization of the diseased loop in a Mikulicz-Paul operation. For an abdomino-

perineal one stage proctosigmoidectomy the incision usually is made parallel with and 3 cm. above the left inguinal ligament.

The liberation of the rectosigmoid follows the conventional plan with the peritoneum divided wide of the diseased pelvic colon and the inferior mesenteric and superior hemorrhoidal vessels doubly ligated and divided rather close to their points of origin. If there is evidence of invasion of the prostate or vagina, this part of the dissection is delayed and made through the perineal wound. A long tape of folded gauze is tied around the sigmoid at the level that will be used to form the perineal anus. This portion of free sigmoid should reach at least 12 cm. (5 inches) below the posterior brim of the pelvis. It should be viable as proved by pulsating vessels; otherwise the descending colon is mobilized sufficiently to enable living intestine to be brought to the perineum. Without forming a pelvic diaphragm, the tape is packed against the floor of the pelvis, the liberated rectosigmoid laid on it and the abdominal wound closed in layers with 32, 30 and 35 gage interrupted alloy steel wire sutures. With this suture material I have had better healing than with catgut in clean and especially in contaminated wounds, and there has been no eventration. If there has been pelvic contamination, a glass "sump" drain is introduced through the abdominal wound and connected with a suction pump while the patient is on the operating table, the aspiration being continued for the first two or three days.

With the patient changed to the lithotomy position the perineal part of the operation is made in one of the following four ways. In any case the anus is first closed with a strong purse string suture and in no case is the withdrawn sigmoid sutured to other tissues.

A. When the cancer has invaded the anorectal region and pelvic floor an anteroposterior elliptic incision wide of infiltrated tissue is made round the closed anus and carried through the pelvic floor to the gauze tape and liberated rectosigmoid, which are withdrawn and a 2 cm. perforated tubular glass drain is introduced posteriorly along the hollow of the sacrum. The wound is lightly closed around the withdrawn rectosigmoid, dressings are applied and the bowel and attached tissue then cut away. A 28 F. rectal tube is introduced and tied in the protruding sigmoid.

B. When the cancer is well above the pelvic floor and is freely movable, a nearly median incision is carried through the pelvic floor from the posterior border of the closed anus along the right side of the coccyx. With the wound well retracted, the tape and attached intestine are gently eased through, care being taken not to make traction on friable cancerous intestine. A perforated glass drain is inserted along the sacrum. Dressings having been applied, the protruding rectosigmoid loop is cut away and tubes are tied in the anal and sigmoid ends, after the anal purse string suture and neighboring gauze packing have been removed. A week later the partitions between the anus and the rectum and the rectum and the sigmoid are divided and the edges sutured, converting the three orifices into one.

C. A somewhat better result has more recently been obtained by dividing the rectal end of the loop just above the sphincters, dividing the anal ring posteriorly and placing the sigmoid in the anal gutter. The intestine is not sutured. The danger of infection from the antisepticized anal mucosa in contact with the wound is not great if there is adequate glass tube drainage.

1. Babcock, W. W.: The Operative Treatment of Carcinoma of the Rectosigmoid with Methods for Elimination of Colostomy, Surg., Gynec. & Obst. 55: 627-632 (Nov.) 1932.

D. When the cancer is attached to the prostate or posterior vaginal wall, an incision curving forward from one tuber ischii to the other is used. The traction tape has preferably been packed somewhat anterior to the rectum. In women an elliptic excision of the posterior vaginal wall is made. The attached vaginal wall or resected portion of the prostate is delivered *en masse* with the rectosigmoid. The rectum is divided by cautery between clamps just above the sphincters, the anal ring being divided anteriorly to avoid constriction and the sigmoid laid but not sutured in the anal groove.

ation is nearly finished. The tied-in rectal tube prevents fecal soiling of the wound until after the drain has been removed and primary adhesion obtained.

The operation may be so planned as to be very radical. From 25 to 65 cm. of intestine with attached lymphatics and soft tissues are delivered through the perineum and removed. In four cases an invaded uterus with appendages and part of the vagina were removed with the rectosigmoid. In others, portions of the vagina, prostate, bladder or small intestine have been resected. In two patients the ureter was divided or

Fig. 2.—Methods of forming a perineal sigmoidostomy: The rectosigmoid, liberated through an abdominal incision, is pulled through the perineum with an attached tape. Method 1, for low lying carcinoma. The anorectosigmoid with lymphatics and pelvic floor has been withdrawn and excised after the placement of dressings. Method 2, the rectosigmoid loop has been withdrawn through a postanal incision. After one week the three openings will be made one by division of the two intermediate partitions. Method 3, the rectosigmoid has been delivered and removed through a postanal incision and amputated and the sigmoid laid but not sutured in the split anus. Method 4, for growths of anterior rectal wall attached to the prostate. The diseased tissues are delivered through an anterior curved incision and removed and the sigmoid end is brought through the anus, which is split anteriorly.

A 2 cm. curved perforated glass tube drain is carried through a stab wound at the right side of the coccyx along the sacrum. The anterior perineal wound and vagina are closed without tension, preferably with buried layer sutures of alloy steel wires. After the dressings are in place, the protruding sigmoid is cut away and a soft rectal tube tied in. It will be observed that the technic eliminates bacterial contamination from crushing or suturing the bowel and that the diseased segment need not be entered or excised until the oper-

ation is nearly finished. The tied-in rectal tube prevents fecal soiling of the wound until after the drain has been removed and primary adhesion obtained.

As the divided sphincters are often retained, a secondary plastic reconstruction of the anal ring was tried in a few of the early cases. Most patients, however, soon learn to regulate their evacuations so well that they consider such an additional operation unnecessary. In some the motor innervation of the muscles has been damaged. In any case a tight or strictural

anal opening gives much more trouble than a wide open one that is properly cared for.

Stage operations to divide the operation into steps or to enable what is at best an inadequate cleansing of the cancerous segment of intestine have not been found of advantage. To the dangers of the first stage there is added a second stage made more difficult by post-operative adhesions and complicated by the danger of contamination of the wound from the openings of the

colon on the abdomen. I have found that the single stage operation may be done with greater facility, in shorter time and with no greater shock than the second stage of the two stage operation. A preliminary enterostomy or an appendicostomy (which may be gradually dilated to admit a rectal tube) is, of course, important if there is preoperative intestinal obstruction.

Perineal proctectomy or proctosigmoidectomy with a perineal anus for cancers lying below the peritoneal reflection is a safer operation (mortality in forty-one cases, 4.5 per cent) than the abdominoperineal operation but has important disadvantages. It does not enable an abdominal exploration, radical removal of tributary lymphatics or, in many cases, an adequate blood supply to the retained bowel. If more than from 15 to 20 cm. of bowel is removed the end of the sigmoid brought to the perineum usually sloughs, and a stricture and cicatricial anal opening results. Nevertheless, on account of its greater safety I consider it the operation to be selected for the lower lying rectal cancers when, because of great obesity, senility or grave organic disease, the mortality of an abdominal operation would be high. An example is a man weighing 278 pounds (126 Kg.), who had an uncomplicated recovery from the perineal operation. As with the combined operation, a perineal glass drain is desirable.

After an abdominal colostomy a collateral circulation to the terminal bowel develops and the retained portion of sigmoid may elongate—conditions favorable to the transfer of an abdominal colostomy to the perineum. The opening is plugged with antiseptic gauze and closed with sutures. The liberated end of the intestine

injure the urethra or bladder, the perineal scar is opened from below and the tape and attached sigmoid are pulled through. A glass tube drain is introduced at the side of the coccyx or through the incision back of the sigmoid. If a ring of abdominal skin has been brought down with the bowel, it may be sutured to the edges of the perineal wound; otherwise the sigmoid protrudes through the perineal wound without suture. It is desirable to fasten a rectal tube in the sigmoid so as to prevent soiling during the first few days after the operation. The glass drain is usually removed in from twenty-four to forty-eight hours.

Palliative colostomy for advanced and inoperable carcinoma of the colon is to be deprecated. The post-operative hospital mortality in my experience is 27 per cent, and often it seems better to use simple decompressive methods or let the patient die obstructed, soothed by opiates and perhaps an intradural injection of alcohol, than to render his last days a burden and offense to himself and friends by a colostomy.

Fig. 3 (case 4).—Colostomy with incisional hernia and prolapse of proximal and distal segments, previous to resection and transfer to the perineum.

I have seen no worth while benefit, and much unnecessary suffering, from the use of x-rays or radium in large dosage in the treatment of well advanced carcinoma of the large intestine or as a prophylactic postoperative treatment.

Ileus is a fairly frequent complication after resection of the large intestine. When not due to diffuse purulent peritonitis, the mortality under proper treatment should be low, for recovery usually follows a simple but early decompression of the distended bowel. Rectal and duodenal tubes with aspiration are first used. If no relief follows, the most distended intestinal coil is carefully localized by physical signs and an overlying 3 to 6 cm. muscle splitting incision made. A small portion of the distended coil is withdrawn, occluded with a soft rubber covered clamp, and a fine silk purse string suture introduced, with which a 14 F. soft rubber catheter is tied in. The intestine is anchored to the edge of the incision, and the small wound is closed around the catheter. Gentle continued irrigations with warm saline solution are continued until the intestine is decompressed. After the decompression the obstruction usually disappears in from twenty-four to seventy-

TABLE 2.—Radical Operations for Cancer of the Colon and Rectum Since January 1930

is covered by a cap of gauze and rubber dam securely tied on with a long tape. The sigmoid segment and, if necessary, the descending colon are then sufficiently mobilized from peritoneal and other attachments to slide at least 12 cm. (5 inches) below the posterior pelvic brim. The soft tissues in the midline close to the sacrum are divided and then tunneled to the pelvic floor until a channel is formed through which the sigmoid may easily be drawn. The tape is packed in this tunnel, the end of the sigmoid laid over the opening and the abdominal wound closed. With care not to

two hours, but the tube should be left in place a week or more. Common mistakes responsible for mortality are delay, prolonged exhausting procedures, as in using evacuants or the Miller-Abbott tube, large abdominal incisions with eventration, introduction of the hand into the abdomen, attempts to liberate adherent intestine, and the use of large caliber rubber tubes for the colostomy, which may cause perforation. If intestinal coils continue to be distended, additional simple enterostomies should be done. Thus in one case an ileostomy, cecostomy and finally a transversostomy was done before relief was obtained. With diffuse purulent peritonitis the mortality is, of course, much higher, but a percentage of the patients can be saved by a similar type of enterostomy or enterostomies and the use of "sump" drains.

Metastasis to the liver was found in twenty-nine cases at operation. In nine the invasion of the liver was far advanced or the primary lesion inoperable. A palliative colostomy was done in six and simple exploration in three. In the remaining twenty cases the

postoperative distention or distress. Not infrequently they were out of bed by the tenth or twelfth day and were discharged from the hospital a few days later. But 25 per cent of the patients died, usually from peritonitis. In separating and delivering cancerous colon, recognized or unrecognized breaks in the bowel or in overlying contaminated tissues frequently occur. The liberated bacteria multiply in residual blood and wound secretion and diffuse in the serum of the peritoneal cavity, causing a spreading peritonitis. Therefore it was found desirable to keep the abdominal cavity free from blood and fluid until isolating adhesions had formed. Four years ago I introduced a method of "internal exteriorization" by anchoring glass tubes of large caliber (lamp chimney drains) over septic intraperitoneal areas or lines of intestinal suture where leakage was feared. Through these open tubes I have observed day by day the very slight reaction of the human peritoneum to glass or air. With glass drains the general peritoneal cavity remains open, free from adhesions and drainable for from forty-eight to seventy-

Fig. 4.—Transfer of an abdominal colostomy to the perineum. *a*, the colostomy is occluded by a cap of gauze and rubber tied on with a long gauze tape. The tape is then packed against the partly tunneled pelvic floor and the abdominal wound closed. *b*, through a perineal incision the tape is grasped and withdrawn with the end of the liberated sigmoid. A perforated glass tube drain is introduced along the sacrum and a rectal tube tied in the protruding sigmoid.

primary growth was resected, with three deaths (15 per cent mortality). A proctosigmoidectomy was done in thirteen, a Mikulicz-Paul stage resection in five and resection with end to end anastomosis in two. The radical operation relieves the patient of obstructive and toxic symptoms and the progressive involvement of the liver usually is painless and at times quite slow. Of the seventeen patients surviving the radical operation, most have survived more than one year and four more than two years. One woman at 75 considers herself in relatively good health more than four years after resection of the splenic flexure.

MORTALITY

Peritonitis has been the predominant cause of death after operations on the colon. By the methods described, the proctosigmoid may be liberated, exteriorized and opened and removed only after the wounds have been closed and dressings have been put in place. Thus the bacterial contamination incident to crushing, dividing or suturing the colon is eliminated. In my earlier experience the wound was closed with little or no drainage. Most of the patients after such a single stage operation then had a rapid recovery with little

two hours. In the dog's abdomen glass tubes and alloy steel wire were found entirely free at the end of two weeks, while gauze, rubber, catgut, silk, cellophane, lucite and wood were buried in plastic exudate and adhesions. Therefore I turned to glass drains and to alloy steel wire sutures and ligatures.

To be efficient, the drain must be dependent or be continuously aspirated by a nontraumatizing suction ("sump" drain). Large tubular glass "lamp chimney" drains anchored over insecure intestinal suture lines or purulent or necrotic areas were found very valuable but if the peritoneal end of the tube is not occluded, an intestinal coil may enter and strangulate, as occurred in three of my cases. With improvements in drainage, the mortality from the single stage proctosigmoidectomy has dropped from 25 per cent to 5.8 per cent, and the mortality from end to end anastomosis of the colon from 22 to 6.2 per cent (table 2). The mortality indicates postoperative deaths occurring during the patient's stay in the hospital. It does not include two deaths of patients with metastatic carcinoma of the lungs or of one patient who could not have the proposed proctosigmoidectomy completed on account of widespread cancerous infiltration in the pelvis. As indicating that

with better drainage peritonitis is not the predominant cause of death, the more recent mortality from proctosigmoidectomy has been due to thyroid crisis from massive intrathoracic goiter (one case) and pyoderma of the abdominal wall (one case).

Operations on patients with perforated carcinoma of the intestine with abscess, internal or external fistula and necrotic soft tissues usually carry a high mortality. This was an important factor in my mortality with the Mikulicz-Paul stage resection (20 per cent). Recent experience indicates that this figure also may be sharply reduced by well placed tubular and aspirating glass drains. In my general series the bladder was invaded in five, the uterus or ovary in five, the ileum in three, the pancreas and jejunum in one and the stomach and jejunum in one, while the vagina or prostate was invaded in several cases. As a rule, the invaded part was resected or removed.

SUMMARY

Superiority of the perineal over the abdominal artificial anus is evidenced by 103 operations in which the sigmoid was brought to the perineum and four operations in which an old abdominal colostomy was transferred to the perineum.

With a perineal colostomy most of the patients are able to dispense with pads or other local protection.

There is slight peritoneal plastic adhesive reaction to glass or alloy steel wire as contrasted with a marked reaction to gauze, rubber, catgut, silk and other substances.

Special glass drains are introduced which have proved of value in preventing and treating peritonitis following resection of the large intestine.

There is a simple and effective operation for post-operative ileus.

Colostomy and heavy irradiation should not be employed in the terminal stage of intestinal cancer.

Alloy steel wire is valuable in the abdominal and perineal closure of clean and contaminated wounds incident to the operations on the intestine.

1720 Spruce Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SWINTON AND WARREN
AND DR. BABCOCK

DR. C. F. DIXON, Rochester, Minn.: The paper dealing with colonic and intestinal polypi emphasizes what can be accomplished if several such lesions are diagnosed early. Robertson is of the opinion that 50 per cent of malignant lesions of the colon and rectum arise from polypi. The classification the authors have worked out seems sound. Polypi of the large intestine may be broadly classified in two groups: Those which stud the mucosa of the colon and rectum would comprise one group. Sometimes one encounters several patients having this condition among members of the same family; no doubt there is a familial tendency toward the disease. Not infrequently the predominant symptom of such patients is hemorrhage of a varying severity. Total colectomy is often indicated. Occasionally, however, the surgeon is able to perform subtotal colectomy and anastomose the ileum to the rectosigmoid and later fulgurate through a proctoscope the polypi within the lower bowel. It has been my experience that a malignant condition invariably develops if these patients do not receive radical surgical treatment. The second group is that in which one or more polypi invade the rectum or colon. The condition is not diffuse polyposis, as is that of the first group. In the case of discrete polyps of the pedicled type, the surgeon may make a trans-colonic approach, remove the lesion along with its stalk and feel sure that a sufficiently radical procedure has been carried out. If the polyp is sessile, as a rule a segmental resection is in order. Fulguration of rectal polypi is often sufficient. However, patients having such polypi should be examined at frequent

intervals. If recurrence is found, further treatment, such as fulguration or resection, should be carried out. The improvement in roentgenologic diagnosis has been a greater step forward in the detection of polypoid lesions of the colon than many realize. Formerly, even though the patient gave a history of bleeding by rectum, roentgenologic observation after a barium sulfate enema would not disclose the presence of a polypoid lesion. Now, by means of the contrast method, expert roentgenologists are able to determine the presence of a polyp which may be no larger than a pea. Regarding the other paper, perineal resection for carcinoma of the rectum and rectosigmoid, without the establishment of an abdominal colonic stoma, will of course not meet with the approval of every one. At present I do not feel qualified to make a definite statement to the effect that any one type of resection for cancer of the rectum or rectosigmoid should be employed as a routine.

DR. W. J. MARTIN JR., Louisville, Ky.: A few years ago it became apparent to me that a good many polyps were being found in my routine examinations of private patients. On collecting these cases it was rather astounding to find that sixty-three polypoid lesions had been found in 1,500 routine sigmoidoscopic examinations, giving an incidence of 4.2 per cent. This is ascribed to three or four factors. One is absolute cleanliness of the bowel. A great number of polypoid lesions are probably missed because so many sigmoidoscopic examinations are done on bowels which are not properly prepared. Another important factor is the position of the patient when one is examining him. The inverted position, with head down, which lowers the diaphragm and allows the lower bowel to be straightened and smoothed out, brings out more clearly any eminence that might be present. Another factor of great importance is proper lighting of the examining instrument. Reflected or proximal lighting is not thought to be as satisfactory as distal lighting. The distal lighting gives a cross light which makes the smaller masses stand out more clearly. Another factor of importance is the preparation of these patients for the roentgenologic examination. Absolute cleanliness is imperative because small amounts of waste material in the bowel may be mistaken for polypoid lesions or vice versa. In some cases of obscure pain or tenesmus in the bowel, with proper roentgenologic examination pedunculated lesions were demonstrated, which was thought to account for the pain. It is believed that if those factors are followed in routine sigmoidoscopic and roentgenologic examinations more of these polypoid lesions will be found.

DR. LOUIS J. HIRSCHMAN, Detroit: Too many of us have been prone to fit the patient to the type of operation rather than fit the operation to the individual patient. The ideal way in which to remove a carcinoma of the rectum and rectosigmoid is the type of operation in which one makes an abdominal incision and can see and feel not only the neoplasm but the surrounding bowel as well and get a good idea of where there are palpable metastases to the liver. When there are large nodules in the liver it is unfair to subject the patient to a great deal of surgery. In the past in some localities there have been many colostomies improperly performed, which have thrown colostomy into disrepute. When a patient is told "You have a carcinoma which should be removed and you must have a colostomy," he replies "I won't have it. So-and-so in my neighborhood has one and nobody will go near him." It is necessary to break down the prejudice of the individual to the colostomy, and there are few patients who absolutely refuse. What most of us consider the ideal is an abdominal colostomy. I prefer a centrally located colostomy to one in the lower left quadrant, for cosmetic reasons. The patient doesn't have a telltale bulge through the clothing, particularly if the patient happens to be a woman and happens to be thin. For this and other reasons a centrally located colostomy is much more to be desired. There are still a few patients who will not submit to an abdominal colostomy, and for those one must have an operation like Dr. Babcock's or the old James Tuttle operation to fall back on. I have performed them, and, strange to say, those patients seemed to get along pretty well. I don't think the incidence of recurrence was any worse and at least they were happy in having the colostomy where they wanted to have it. So far as I am concerned, if a patient wants to keep clean, he had better have it where he can see it rather than some place where he can't see it.

DR. FRANK H. LAHEY, Boston: I am sure that you as gastro-enterologists are interested in whether a colostomy in an operation for cancer of the rectum is in front or in back, but I am equally sure that that is not the problem I should discuss with you. After all, that is a technical problem for surgeons to have their individual opinions about. The most interesting part of Drs. Swinton and Warren's statistics has to do with the fact that they have taken 100 cancers of the rectum, 100 cancers of the left colon and 100 cancers of the right colon, all proved by removal at operation, and demonstrated that, in terms of pain, altered bowel function or blood in the stools, 97.7 per cent of these cases give such evidence. In other words, when but 2.3 per cent of 300 proved cases of cancer of the colon and rectum fail to have in the history the evidences of an alteration in bowel function, the diagnosis should be made earlier than it is. Another thing that ought to interest gastro-enterologists is figures of nonrecurrence after radical removal in malignant lesions in these locations. Forty-seven per cent of our patients with carcinoma of the rectum who have had the radical operation are alive and well over five years without recurrence, and 42 per cent of those whose colons were affected. Equally good figures have been reported by other surgeons who are particularly interested in this subject. They do demonstrate, however, that this is a particularly favorable lesion from the point of view of five year nonrecurrence. I do not want to discuss the technical side of surgery of cancer of the colon and rectum but I do want to present some convictions to you as gastro-enterologists which I think are important and which I definitely think have to do with increasing the number of patients who are cured or at least have long periods after operative procedures without recurrence of the lesion. At the Lahey Clinic we are seeing patients in considerable numbers with carcinoma of the colon and rectum, who have had their abdomens opened and have been closed as inoperable when we have proved by reoperation that they were not inoperable. I speak particularly of the matter of contact carcinomas.

DR. NEIL W. SWINTON, Boston: I was interested to hear Dr. Dixon's remarks on the comparison of these polyps. I think we are particularly indebted to Dr. Martin for his emphasis on the necessity for careful preparation of these patients for proctoscopy and sigmoidoscopy. Adequate preparation makes it possible to examine carefully all of the mucosa surface of the rectum and rectosigmoid so that no polyps will be missed.

DR. W. WAYNE BABCOCK, Philadelphia: Abdominal discomfort, usually not recognized as colic, which may follow intake of food or other exciter of peristalsis, is the common but often ignored first symptom of intestinal carcinoma. It may precede melena or obvious change in bowel habit by months or even a year or more. In my experience nearly all patients object to an abdominal colostomy, while those with a functional perineal opening are grateful that it is not on the abdomen. Those who have had the abdominal opening moved to the perineum tell us that they are now more constipated, have much less soiling or escape of offensive gas and better expulsive effort than before, and that the opening is much more conveniently cared for. The gas from the abdominal colostomy was so objectionable that the woman bank clerk mentioned had lost her job, while the physician as well as a business man who had found it necessary with the colostomy to irrigate several times a day now can go without a pad by emptying the colon by enema once every three or four days. With a perineal opening one young woman has married, while a second has had an abdominal colostomy transferred, apparently in the belief that she could then marry. Possibly evacuations and the discharge of gas are less frequent with the perineal opening because the colon can then be more conveniently irrigated or completely emptied. Irrigation and thorough emptying of the colon with the necessary use of large quantities of water is a messy procedure with the abdominal opening, even though the patient sits in a bath tub. The colon may be compared to a storage tank that overflows when filled. Thus soiling from a colostomy opening is a sort of "incontinence of overflow," which usually can be obviated by regulated emptying of the large bowel: the patient must find out for himself whether this should be every day or every three or four days.

Except with patients with stricture or recurrence or those of such social or mental status that they cannot or will not attend to personal hygiene, there should be little involuntary soiling with a perineal colostomy. However, usually it requires about three months after the operation for a regulated adjustment to be established. Finally, the expulsive action of the abdominal muscles is more effective when the opening is on the perineum than when it is above and then I think the apposed buttocks offer some bar to escape of gas, which therefore is retained and in part absorbed.

SOME PROBLEMS IN THE PATHOLOGY OF NEUROTROPIC VIRUSES

LESTER S. KING, M.D.

PRINCETON, N. J.

With regard to virus infections of the nervous system, generalizations are of limited validity. In the study of any single disease, plurality of strains of the virus, relative susceptibilities of various experimental animal species and differences between natural and experimental hosts offer serious complications. And different diseases seem to behave in quite different fashion. Only isolated data are available, and inferences can be suggested rather than proved.

With this word of caution, three arbitrarily selected topics may be critically examined.

THE SIGNIFICANCE OF THE NASAL PATHWAY IN INFECTION.

The possible importance of the nasal pathway in poliomyelitis has received the attention of investigators for many years. In 1912 Flexner and Clark¹ showed that monkeys might be experimentally infected by the application of virus into the nose and that in such cases the virus localized first in the olfactory bulbs. Faber and Gebhardt² demonstrated the orderly progression of the virus through the neuraxis, following intranasal instillation, in a manner consistent with the hypothesis of nerve spread. If the nasal pathway is interrupted, instillation of virus is without effect. Brodie and Elvidge³ and Schultz and Gebhardt⁴ proved the effectiveness of surgical interruption, while Armstrong and Harrison and others⁵ showed a similar protective

effect from chemical tanning of the nasal mucosa prior to attempts at infection. According to Lennette and Hudson⁶ intravenous administration of virus to animals whose olfactory paths have been surgically interrupted is without effect, although controls died. Armstrong⁷ showed that tanning of the nose greatly reduced the effectiveness of intravenous administration. This work suggests that virus in the blood stream is first deposited on the olfactory mucosa and from there passes into the brain.

It is of importance to recognize that most of the work just mentioned was done with strains of virus that are relatively noninfectious by subcutaneous or other methods of inoculation. Recently Sabin⁸ has shown that the tonsillopharyngeal region is more sensitive to injections of virus than many other regions of the body. This and the work cited, coupled with the observations of Aycock and Luther⁹ that in many cases bulbar poliomyelitis in man follows tonsillectomy, strongly implicate the nose and nasopharynx together as the normal portal of entry in the natural disease.

Strong and independent supportive evidence is furnished by the recovery of virus by numerous investigators from the nasal washings of human patients in various stages of the active or abortive disease or of healthy carriers. This work has recently been summarized by Kramer and his associates.¹⁰ Furthermore, virus has been recovered from the stools of human patients (work summarized by Kramer¹⁰). It has been shown experimentally by Levaditi and others¹¹ that virus which has been fed may be recovered from the stools. The recovery of virus from the stools with the naturally occurring disease has been attributed to the swallowing of virus-containing nasal secretions. This is generally considered as further evidence that localization on the olfactory mucosa is a stage in the pathogenesis of the natural disease.

There is, however, much evidence which does not harmonize with the idea of the nasal route as the pathway of entrance. Haber¹² showed that section of the olfactory bulbs did not always prevent infection after intranasal instillation, and others¹³ have demonstrated that the nasal pathway is not the only mode of entrance of the virus into the nervous system after intravenous injection.

Most of the experimental work has been carried out with strains of virus that had undergone repeated animal passage. Recently isolated strains may behave quite

differently. Trask and Paul¹⁴ have convincingly shown that strains of virus freshly isolated may be highly infectious by cutaneous inoculation, although this property tends to diminish or to be lost with repeated monkey passage. The long-passaged strains used to demonstrate the significance of the nasal pathway, for example the Rockefeller MV strain,¹⁵ are relatively harmless on cutaneous inoculation.

Another example of change in properties with passage is furnished by Kling and his co-workers.¹⁶ Simple feeding at first resulted in a high percentage of infection. But with repeated passage over a period of years the percentage of infection by this route sharply diminished. With the strains used by German and Trask,¹³ infection was not due to deposition of virus from the blood on the olfactory mucosa, with subsequent passage along the olfactory nerve. Bilateral olfactory neurectomy did not prevent experimental poliomyelitis after intravenous or intracutaneous inoculation. Infection even resulted from inoculation into completely denervated areas in which the blood supply was intact.

In the natural disease there is independent evidence against the significance of the nasal route. The epidemiology is one important aspect. The incidence of poliomyelitis does not harmonize with the incidence of known respiratory infections. Further evidence is furnished by pathologic studies. Experimentally infection by the olfactory pathway gives rise to characteristic pathologic features in the olfactory bulb, recently considered by Sabin and Olitsky.¹³ With regard to the human disease there are only a few observations on the histologic state of the olfactory bulbs, but these are all negative. Smith¹⁷ found "surprisingly little" change in a series of fifty-six bulbs from forty patients. Harmon¹⁸ obtained similar negative results. Sabin (a personal communication) also studied bulbs from twelve human patients, and in no instance was there evidence of the passage of virus. However, he stated that clinically most of these patients gave a history of the bulbar type of the disease. The negative evidence weakens the case for the importance of the olfactory pathway in the natural disease, a conclusion already reached by Smith. Further studies on this subject are urgently needed.

A point of considerable interest is the recovery of virus from nasal washings and stools of human patients. Clearly these observations in naturally occurring cases indicate a mode of excretion of the virus. A problem of theoretical interest is thereby posed. In opposition to earlier work considering poliomyelitis as a systemic disease, more recent work¹⁹ has considered that virus as strictly neurotropic, that is, not multiplying except in nerve tissue. If this is correct, the problem thus arises: How does the virus get out of the nervous system?

In the olfactory mucosa it is possible that virus-charged nerve cells in the epithelium in some way discharge the virus into the secretions, while the nonnervous portion of the epithelium plays no part. A little reflection shows that the quantity of virus so discharged must be enormous if, say, enough is going to persist unchanged through the intestinal tract and be recovered in the stools. Considering the enzymatic action and the p_H alterations encountered on such a voyage, and considering the lack of sensitivity of the test animal, the amount of virus produced must originally be very great. If the virus multiplies only in nerve cells, the problem of excretion by nerve cells into a fluid medium is raised. One of the principal objections to accepting this point of view is that in the cranial cavity, where nerve tissue has free access to the cerebrospinal fluid, the virus can be demonstrated in this fluid only with the utmost difficulty, if at all. Considering the relative number of nerve cells in the brain and the ease with which concentrated spinal fluid may be gathered, it does not seem likely that nerve cells exude virus into their fluid environment. The relatively few nerve cells in the olfactory mucosa (and the greater technical difficulty of collecting nasal secretions to demonstrate virus) make it seem unlikely that the virus in the olfactory mucosa is restricted to the neural elements. This problem also awaits further investigation. It seems to me that there is no natural disease which can be called strictly neurotropic and that poliomyelitis, to some extent at least, is a systemic disease. In this connection Brodie and Elvidge,³ while claiming that experimental poliomyelitis is entirely a central nervous system disease, held it not proved that the natural disease is equally so.

The work so far presented indicates that in experimental poliomyelitis special ease of infection by the olfactory route, together with the general importance of this portal of entry, is a property of certain strains of the virus. But with fresh strains the subcutaneous route may be highly effective, a property that is readily lost. Since the monkey is at best a poor host, the production of disease by moderate doses given intracutaneously appears of great significance. Of equal significance is the fact that cutaneous infectiveness is impaired by repeated passage. It is possible that the relative importance of the nasal route in experimental poliomyelitis is purely an artificial condition, brought about by some degree of change in the virus and without necessary relation to the natural disease. There are other diseases which furnish suggestive analogies and parallels on this point.

Recent work²⁰ with equine encephalomyelitis virus may be briefly summarized. Both fresh and fixed²¹ strains of virus were used, both highly virulent after intracerebral inoculation. But with peripheral inoculation the behavior is different.

In adult mice, with the fresh strain, any peripheral route of inoculation is effective. Injections into the peritoneum, subcutaneous tissue or eye and instillation into the nose result in infection, with but little difference in virulence for any of these routes. On the other hand, fixed virus injected subcutaneously is nonpathogenic, although the same virus placed in the nares or

injected into the eye is active in high dilutions. Infection by the ocular or nasal route, while less effective than by the intracerebral pathway, is far more virulent than any other mode of peripheral inoculation. With the fresh, recently isolated strain this difference does not exist.

In guinea pigs,²² fixed virus injected into the eye could be traced with utter constancy along the appropriate nerve paths in the brain. When injected into the eye, the fixed virus first infects the ganglion cells of the retina. Once the cell body has become involved, the virus, in a manner yet unclear, passes along the axons constituting the optic nerve.

The anatomic considerations of the olfactory system provide a similar explanation of the effectiveness of intranasal instillation of virus. The cells of origin of the olfactory nerve are located directly in the olfactory mucosa, so that virus applied to the mucosa infects the cell body first. The axon, the prolongation of the cell body, becomes secondarily involved.

Primary infection of the axon with subsequent involvement of the cell body rarely occurs. Injection of fixed virus directly into the sciatic nerve produces infection infrequently, even with high concentrations of virus.²⁰

With fixed virus, the heightened susceptibility to intranasal as compared with, say, subcutaneous inoculation is due to several factors. One is that this strain of virus, to infect the nervous system with any but enormous doses, must first involve the cell bodies of the neurons; the second, that in the nose the cell bodies are superficial in the olfactory mucosa, with corresponding ease of infection. Similar considerations apply to intra-ocular injections. Nerve filaments or endings, such as are encountered with subcutaneous injections, are not the equivalent of nerve cell bodies.

Ease of infection by the nasal route, in the face of relative refractoriness of other peripheral sites, is found with other viruses. The neurotropic strain of yellow fever virus, produced by passage of the natural virus through mice, behaves similarly. Adult mice, demonstrated by Theiler²³ to be refractory to intraperitoneal inoculation, will succumb only if there is simultaneous brain injury.²⁴ Recently, however, Findlay and Clarke²⁵ showed that intranasal instillation of virus without brain injury is readily followed by encephalitis. Louping ill has been shown by Webster and Fite²⁶ to be infectious for mice when given intranasally, but subcutaneous or intravenous inoculation is without pathologic effect.²⁷ In the intact mouse the virus of St. Louis encephalitis infects only with difficulty after intraperitoneal inoculation but readily by the nasal route.²⁸

When, however, the natural diseases are studied, the direct nasal portal of entry is of no apparent significance. Louping ill in nature is transmitted by the tick

Ixodes ricinus.²⁰ Equine encephalomyelitis, with overwhelming probability, is carried by mosquitoes.³⁰ Yellow fever in nature does not produce encephalitis, but the usual viscerotropic virus may be neurotropic for mice,³³ and for monkeys the virus has been shown to harbor a neurotropic component that can be disclosed by a suitable experimental method.³¹ Yellow fever, of course, is also insect borne. The mode of transmission of the St. Louis encephalitis B is not known; mosquitoes may be artificially infected but have not been shown to transmit the disease by biting.³² But the Japanese encephalitis B, which, though serologically distinct from the St. Louis type, has many points of similarity, has been shown susceptible of transmission by mosquitoes.³³ These few examples suffice to show that certain viruses which in their natural condition are highly infectious by subcutaneous inoculation may with altered conditions show a predilection for the olfactory pathway.

It is of interest that in fox encephalitis, which was studied in its natural host, strong evidence has been adduced by Green and his associates³⁴ that the nose, or at least the respiratory tract, may be the natural portal of entry for the virus. This evidence only shows, however, how the virus may gain access to the body. The modes by which it then reaches the brain have not yet been demonstrated.

Experimentally, under conditions not yet understood, the olfactory neurons may at times furnish an indirect mode of entrance into the nervous system. But at present there is little evidence that in naturally occurring virus diseases of the nervous system the nose is the direct portal of entry from which viruses pass into the brain. Under the conditions of experimentation this pathway has received great prominence, but the necessarily artificial character of the data must be kept in mind.

THE HEMATO-ENCEPHALIC BARRIER

There are relationships discernible between the action of certain viruses and that of certain vital dyes. With the acid dyes, such as trypan blue, it has been abundantly shown that the adult brain does not stain vitally under normal conditions. But brain trauma allows the dye to penetrate the injured tissue. Furthermore, in infant animals the dye will penetrate more easily into the brain than is the case with adults. This entire subject has been discussed at length elsewhere,³⁵ and certain exceptions to the statements just made have been noted.

There are striking parallels between these facts and the action of certain viruses. These may be considered under two headings:

The Facilitating Action of Brain Trauma.—Certain viruses are harmless if injected intraperitoneally into adult mice; but if at the same time there is a nonspecific brain injury, such as the injection into the brain of a weak starch solution, the intraperitoneal inoculation results in fatal encephalitis. This was shown for yellow fever virus by Sawyer and Lloyd.²⁴ A similar phenomenon occurs with the virus of St. Louis encephalitis.²⁸ Here, although the concentrated virus is lethal when given intraperitoneally, significant dilutions are fatal only after concomitant brain injury.

With other hosts and other viruses, comparable data are available. With poliomyelitis virus, Flexner and Amoss³⁶ first demonstrated the facilitating effect of meningeal irritation in producing infection after various routes of inoculation. Others³⁷ have shown that parenchymatous damage to brain tissue was similarly effective. German and Trask³⁸ found that peripheral injury, such as operations on the extremities, may facilitate infection. Here the central nervous system was not directly involved.

With Borna disease virus, Zwicky, Seifried and Witte³⁸ showed that cutaneous inoculation was regularly infective only after nonspecific brain trauma. Similarly, in rabies³⁹ there is a facilitating effect on peripheral inoculations if spinal fluid is pumped back and forth.

However, not all viruses show this behavior. Vesicular stomatitis and equine encephalomyelitis are highly infectious with direct intracerebral inoculation. Yet when injected peripherally their encephalitogenic power is not increased by concomitant brain injury.⁴⁰

Increased Susceptibility of the Infant Organism.—With certain viruses infant animals, especially mice, are much more susceptible to peripheral inoculation than are adults of the same species. This was first shown by Theiler²³ for the virus of yellow fever and by Andervont⁴¹ for certain strains of herpes virus. More recently the phenomenon has been studied by Olitsky and his associates⁴² with vesicular stomatitis viruses, in which the disparity between infants and adults was marked with the particular strains employed. Equine encephalomyelitis virus has also been studied from this standpoint.⁴³

That injury facilitates the passage of virus and of trypan blue into the brain, and that the infant brain

is more receptive to some viruses and to trypan blue than is the adult organ, are rather surprising parallels, which may be merely unrelated coincidence or may suggest some deeper uniformity.

The reasons why a cerebral trauma facilitates infection after peripheral inoculation are not at all clear. The simple explanation of a "barrier" which has been broken down, as if a hole had been knocked in a fence, seems scarcely tenable. If such a rupture in the "barrier" were correct, one would expect that brain trauma, with peripheral injection, such as by the intravenous route, would allow any virus to pass in readily, making a situation comparable to intracerebral injection of virus. With some viruses this does not occur. The situation is undoubtedly much more complicated.

With vital dyes, the most satisfactory explanation for staining of an injured area is a change in the binding power, or "affinity," of the tissue toward the dye.³⁵ It seems likely that a comparable explanation may apply in the case of certain virus infections. As a substrate for virus activity, tissue which has been altered by injury presents different properties from normal tissue. Virus in contact with this altered tissue may behave differently from virus in contact with normal healthy tissue. But experimental work is necessary to establish the validity of this speculation.

With respect to the special behavior of infant animals, especially mice, toward some viruses, differences in the tissue must also be kept in mind. From the anatomic and biochemical standpoint the immature nervous system of infant animals of most species is distinctly different from the adult stages. The role of these factors for vital staining has been emphasized elsewhere.³⁵ The intrinsic differences between immature and mature nerve tissue may constitute the alterations in substrate required to explain the variation in behavior of infant and adult animals toward some viruses.

Although this subject is clearly in need of detailed study, one fact stands out, namely, that some change in the character of nerve tissue is the one connecting link between (a) the increased susceptibility of infants as compared with adults and (b) the increased susceptibility of injured as compared with normal animals. The changes in the two instances are obviously not the same. It is possible that there is nothing in common between the two sets of phenomena or between the action of some viruses and that of certain vital dyes; but the parallelism between virus and dye action exists and should be pointed out. Only future work can determine the significance of this parallel.

CONSIDERATIONS ON HISTOPATHOLOGY

There are three cardinal points in the pathology of virus diseases of the nervous system: inclusion bodies, cellular necrosis and inflammation. These three need not all be present. In pseudorabies in the rabbit, for example, inclusion bodies may be the only sign of disease, and inflammation as well as frank necrosis may be absent. Furthermore, none of these features are in any sense specific for virus diseases. Nevertheless they furnish a constantly recurring pattern which must be explained.

Viruses are generally considered as obligatory intracellular parasites. The question has been raised whether neurotropic viruses primarily attack the nerve cells. Many viruses have been shown to travel along nerve paths. Injury to the cells harboring the virus might logically be expected as the first step. In some cases,

under experimental conditions, nerve cell damage has been shown to precede any inflammatory change. This damage may take the form of inclusion bodies as, for example, in poliomyelitis,⁴⁴ where changes in anterior horn nerve cells may precede any inflammation; or there may be extensive loss of neurons without significant reaction, such as occurs in the cerebellum in louping ill.⁴⁵ The whole subject has been well reviewed by Hurst.⁴⁶

There are observations, however, which do not harmonize with the view of primary attack on neurons. In experimental St. Louis encephalitis²⁸ and equine encephalomyelitis⁴⁷ the first alterations are clearly inflammatory and interstitial. This is of special interest in equine encephalomyelitis, for this virus may invade the brain directly through the blood stream but may also travel along nerve paths.⁴⁸ It may attack the tissue after axonal transmission or attack through the blood vessel wall, but in either case it provokes an interstitial reaction as the first response.

With reference to the cell damage found in virus encephalitis, it is important to remember that selective neuronal necrosis occurs in nonvirus diseases such as various circulatory and toxic disturbances. The most familiar examples include the selective loss of pyramidal cells in the hippocampus, the granule cells of the fascia dentata remaining intact; the selective destruction of Purkinje cells in the cerebellum, and the scattered areas of neuronal loss, or "verödungsherden," in the cerebral cortex. To this type of damage inflammatory response may be absent or insignificant. The occasional inflammatory cells that are inconstantly seen in such reactions are considered by neuropathologists as "secondary" inflammation, in the sense of a reaction to necrotic tissue however produced. In marked contrast to this is the vigorous inflammatory change seen in various forms of encephalitis, even where there is no necrosis of tissue.

When forms of virus encephalitis are compared with other forms of pathologic alteration of the brain, it is clear that cellular necrosis and inflammation may vary quite independently of each other. Either one may occur with little or no indication of the other. As a class, the virus encephalitis are primary inflammatory conditions. The degree of neuronal damage is totally inadequate to account for the mesodermal response on the basis of a nonspecific reaction to injury however produced. The distinction between a secondary inflammation clearly dependent on extensive necrosis and a primary inflammation which may be quite independent of necrosis is valid.

It might be suggested that in virus encephalitis there are both inflammatory and necrotizing components. It would be misleading to call either one primary and the other secondary. Although, of course, sufficient inflammation however produced will invariably

injure cells, while extensive necrosis from whatever cause may provoke a slight inflammatory reaction, nevertheless these two components have no necessary connection with each other. In some diseases and in some hosts one type may prevail; in another host the same virus may provoke an entirely different response. This is well illustrated in louping ill, with which, according to Brownlee and Wilson,⁴⁹ the pig shows an intense inflammation with insignificant cellular necrosis, while in other hosts abundant necrosis is present. The difference in behavior can only be ascribed to host factors. These two components must be considered as correlative in their action, one predominating under certain conditions, the other under different circumstances.

In relation to the neuronal changes found in many virus diseases, the reaction produced by a nontransmissible nonviral agent is of considerable significance. This agent, present in monkey bone marrow as well as in other tissues of other animals, is widely known as a result of the Gordon⁵⁰ test for Hodgkin's disease. On injection into guinea pigs or rabbits it causes a characteristic encephalopathy.⁵¹ The principal and invariable feature is a selective loss of Purkinje cells of the cerebellum. In the early stages cells show well marked intranuclear acidophilic inclusion bodies, indistinguishable from those described for poliomyelitis or equine encephalomyelitis. At a slightly later stage ectodermal glial nuclei also show acidophilic inclusion bodies. A change less constant than Purkinje cell loss is a symmetrical necrosis of the pyramidal cells of the hippocampus, again with absent or insignificant inflammatory changes. It is of interest, then, that a nonviral agent can cause selective necrosis of nerve cells, with formation of inclusion bodies as a stage in the process, by action that appears to be indirect.

Comparison may be made with certain virus diseases. Hurst⁴⁶ commented on the frequency with which hippocampal necrosis occurs in rodents in a variety of diseases. Selective loss of Purkinje cells is pronounced in louping ill⁴⁵ and somewhat less marked in many other diseases. The similarities between some virus diseases and the encephalopathy from bone marrow extract are striking.

Although it is not known how viruses act on the brain, a tentative separation into direct and indirect action seems plausible. By direct action is meant the immediate interaction between virus and tissue. The nature of this reaction varies according to the animal host. With equine encephalomyelitis virus in the guinea pig, for instance, the direct action would be exemplified by disseminated focal lesions, in which inflammatory changes appear first with more or less cell necrosis later.

By indirect action is meant the initiation of a train of events leading primarily to cell necrosis, effected by means shared by nonvirus agents. The type of massive hippocampal necrosis, for example, found after intracerebral injection of equine encephalomyelitis is too similar to that produced by normal monkey bone marrow to be dismissed as a coincidence. An underlying common factor, not specific to either, must be assumed.

Similar considerations may apply to the sequence of intranuclear inclusions followed by neuronal necrosis, as shown, for example, by poliomyelitis and this same bone marrow agent, or to the phenomenon of selective Purkinje cell necrosis.

It would be premature to speculate on the underlying bases of such changes. It is worth noting, however, that in many virus encephalitis there occur disseminated areas of damage that may be called primary and other types of injury that may be called secondary and indirect. Such a distinction may not be valid for all viruses or for all susceptible hosts, but the possibility of such a distinction must be kept in mind in the study of any virus pathology.

CONCLUSION

The material of this paper does not lend itself to summary. From all the data here presented, the only conclusion that can satisfactorily be drawn is that but little is known of the interaction between viruses and the nervous system. As yet there is only fragmentary evidence. Only future work, with unremitting critical examination of data and doctrine, can lead to a sound basis of understanding.

ABSTRACT OF DISCUSSION

DR. ROBERT G. GREEN, Minneapolis: The problem of determining the mode of passage of the viruses into the central nervous system has been well considered by Dr. King. The reverse process also has a critical bearing on the subject. A virus, like any other biologic parasite, after reproduction must escape to a new host to perpetuate its species. It may be that many viruses which produce disease of the central nervous system grow sufficiently for species perpetuation in some surface area such as the upper part of the respiratory tract and that invasion of the central nervous system is entirely accidental. Regardless of whether or not a virus must escape from the central nervous system, a demonstration of its actual passage to the exterior and of the manner in which it progresses must be valuable in the solution of this problem. From a closed intramuscular or intracranial injection, the virus of fox encephalitis soon appears in the nasal cavity. Since the virus is found in the blood stream and since it does not attack nerve tissue, the virus must be blood borne to the nasal location. The complexity of the hemato-encephalic barrier is clearly shown in the special case of the fox encephalitis virus. In the natural disease this virus is distributed throughout the brain but only in association with endothelial cells. It never penetrates sufficiently to involve the ependymal cells lining the cerebrospinal circulatory system. If the virus is introduced into the cerebrospinal fluid, it at once attacks the ependymal cells. It may be that the early inflammatory reaction of viruses discussed by Dr. King is, as he suggested, an extracellular effect of viruses; or the early growth of the virus in the cell may produce disturbances in the cell metabolites which call forth an inflammatory response. In my experience the same virus may produce cell destruction with no inflammatory response in some animals and in other individuals of the same species may provoke an intense inflammatory response with few cells showing any specific effect of the virus. However, as viruses seem to be incomplete microbes, some of those less highly adapted and simplified might be considered to carry on their parasitic processes between cells in close proximity to the cell membrane rather than within the host cell protoplasm.

DR. RICHARD B. RICHTER, Chicago: I am gratified at the remarks about the significance of the olfactory pathway. In this country, at least, the experimental evidence that suggested the olfactory pathway to be the significant one in natural disease has been emphasized at the expense of the evidence against it, especially for poliomyelitis. I think Dr. King's conclusion that this route is unimportant in the natural disease is valid for the group of diseases which he is considering, particularly polio-

myelitis, St. Louis encephalitis and equine encephalomyelitis. These are diseases which have similar epidemiologic manifestations, which are seasonal in late summer and in which there is virtually no evidence of any contact communicability. But the possibility of natural infection by way of this pathway may be of great significance for other types of encephalitis, notably for lethargic encephalitis, a disease attacking by preference in the winter months and notoriously associated with respiratory infections. There is some reason to believe that here direct contact infection occurs. The speculation which Dr. King has made about the hemato-encephalic barrier is interesting. When Nissl first introduced this conception his idea was that the barrier was represented anatomically by the adventitia of the cerebral blood vessels and it is now spoken of as a brain-blood barrier and the idea has been gradually formed that it is sort of a mechanical wall. Undoubtedly the situation is more complicated than this, but I do think that there are some considerations which point to the pial-glial apparatus of the brain as being a true biologic barrier and the site of much of the defense of the brain against toxins and infectious agents. I cite the older experimental results of injecting micro-organisms into the blood stream with and without concomitant trauma to brain or cerebral vessels. Without such trauma there is relatively little involvement of the brain. With it there is much and the infectious process becomes precisely localized at the point of injury to the tissue. Dr. King's suggestions as to the nature of damage to nerve cells from viruses is also of great interest. In the light of such clear-cut experiments as those of Goodpasture, for example, on the transmission of herpes and rabies virus along axons with direct involvement of the nerve cells, it is hard for me to give up the idea that such direct action is the most important feature.

DR. L. S. KING, Princeton, N. J.: I am glad that Dr. Green raised the point of the invasion of the central nervous system as merely an incidental factor in infections. Poliomyelitis has been given as an example of a purely neurotropic disease which invades only the nervous system. I feel that Dr. Green does not agree with this, and I do not agree with it. In all probability there is no such thing as a purely neurotropic virus; all encephalitis are systemic diseases, and the invasion of the nervous system is more of an incidental factor which may occur in some cases and may not occur in others. The reason the central nervous system is involved in some persons and not in others is as yet unknown. I am glad that Dr. Green does not believe viruses are necessarily intracellular parasites. Viruses can multiply only in the presence of living cells, but that is different from saying that viruses can multiply only in living cells. I feel that probably viruses are not necessarily intracellular parasites. They can multiply only in the presence of living cells, but multiplication may, of course, be extracellular. Dr. Richter raised the point of von Economo's encephalitis. The point he has raised is a valid one, but this virus is lost, and there is no way of carrying on experimental studies. The hemato-encephalic barrier probably has a locus in the sense of an interface. The capillary endothelium marks the interface between the blood and the brain tissue. But that is quite a bit different from saying that the barrier consists of the capillary endothelium, which is the point against which I wish to protest. The barrier, in my mind, lies in an interaction between three substances: the blood, the membrane (that is, the capillary endothelium) and the brain. Obviously the membrane, the capillary, is the division between the two systems. Although that is the site, it is not the barrier in the sense of a structure which of itself keeps things out. Concerning the transmission of virus along the nervous system, demonstrated in the experiments of Goodpasture and others, the property of living only inside nerve tissue is frequently a property only of a fixed virus. Viruses which primarily travel up nerves are those which, by modification, can multiply only inside of nerve tissue. Some viruses will multiply in many kinds of tissue. Under certain altered conditions, such viruses retain the faculty of multiplying only in nerve tissue and have lost the power of affecting other tissues. The strains of herpes virus which travel up nerves seem to be precisely those strains which have lost the faculty of multiplying in non-nervous tissue and multiply only within the nerve tissue.

MAPHARSEN IN TREATMENT OF SYPHILIS IN OFFICE PRACTICE

A STUDY BASED ON 2,342 INJECTIONS OF
113 PATIENTS

CHARLES R. REIN, M.D.

AND

FRED WISE, M.D.

NEW YORK

Our purpose in this paper is to discuss the value of mapharsen in the treatment of syphilis by the physician in his private practice.

It is known that the majority of syphilitic patients undergoing treatment in private practice are in the late asymptomatic stage and that the diagnosis of syphilis is frequently made solely on serologic evidence.

Now that most states have, or soon will have, legislation requiring routine premarital and antepartum blood tests, many more latent asymptomatic syphilitic persons will be detected and will undergo treatment in clinics or in private practice. It has been estimated that between 50 and 90 per cent of syphilitic patients treated in private practice are asymptomatic. It is especially with regard to this large group that the determination of the diagnosis rests, in large measure, on the outcome of the serologic examination.

One of the great difficulties encountered in private practice is to convince patients with latent syphilis that sustained treatment must be carried out. Aside from economic considerations, one of the most important reasons for irregular and haphazard attendance and eventually for complete relinquishment of treatment is the production of various untoward reactions by the standard arsenical preparations in common use. Such reactions—often alarming and at times dangerous—in patients who before therapy had no symptoms relative to their infection play an important role in discouraging them from continuing the necessary treatment.

It is therefore an indispensable part of treatment to avoid the therapeutic reactions which so often are stumbling blocks in the path of an otherwise uneventful series of injections and handicap the practitioner in the free use of the arsenicals. If, for these asymptomatic patients, a preparation that produced a minimum of untoward reactions was used, it would be an added inducement toward faithful adherence of the patient to the prescribed courses of therapy.

Such a preparation is available in the form of meta-amino-parahydroxyphenylarsine oxide hydrochloride, a trivalent arsenical identical with arsenoxide and designated by Tatum and Cooper¹ as mapharsen. This preparation has been thoroughly investigated and many reports have been published to attest its effectiveness in producing early sterilization and disappearance of spirochetes in open primary lesions, with rapid healing of concomitant and later clinical manifestations, and in

The mapharsen used in this study was supplied by Parke, Davis & Co., Detroit.

Dr. Girsch Astrachan and Dr. Samuel B. Frank furnished some of the material used in this study.

From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University.

Read before the Section on Dermatology and Syphilology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

effecting and maintaining a reversal of serologic reactions within a reasonable length of time.²

We were especially interested in reports pertaining to the relatively low toxicity of therapeutic doses, the absence of severe nitritoid reactions, and freedom from reactions, except those affecting the gastrointestinal tract. Moreover, up to the present time no fatalities have been encountered which resulted from therapy with mapharsen.³

CLINICAL MATERIAL

This report embraces observations of all patients who received mapharsen over a period of thirty-four months. A total of 113 patients received 2,342 intravenous injections, with an average of 20.7 injections per patient. This series consisted of sixty-five males and forty-eight females. Their ages ranged from 13 to 70 years, with an average age of 37.7 years.

The initial dose was 20 mg., and this was increased to 40 mg. for females and 60 mg. for males. (Some of the heavier females received as much as 60 mg., while some of the slighter males were maintained at a 40 mg. dosage.)

Of these 113 patients, eighteen (15.9 per cent) applied for treatment because they had clinical evidences of syphilis, manifested individually as chancres, secondary eruptions or gummas. Twenty-three patients (20.3 per cent) consulted their physicians for a serologic recheck because they knew they had, or had had, syphilis and wanted to determine their present serologic status. Of these twenty-three patients, the condition of approximately 50 per cent was originally diagnosed as syphilitic by routine blood tests. For the remaining seventy-two patients (63.7 per cent) the diagnosis of syphilis was made solely by routine serologic examinations. When these patients were carefully questioned regarding their infections, eighteen admitted knowledge of a previous infection and treatment. The remaining fifty-four patients stated that they never knew they had the disease.

In this group of 113 patients, eighty-three were asymptomatic. Eighteen patients presented clinical evidence of cutaneous syphilis, and five instances of cardiovascular syphilis were detected by electrocardiographic studies, while spinal fluid examinations disclosed that seven patients had asymptomatic syphilis of the central nervous system.

THE THERAPEUTIC EFFICACY OF MAPHARSEN

Owing to the fact that most of the patients treated in this series were in the latent or asymptomatic stage (that is, they had no symptoms referable to their dis-

ease), we had to depend on the serologic observations to determine the efficacy of the drug. Blood tests were made on all patients before the institution of mapharsen therapy. Twenty-four patients (21.2 per cent) discontinued treatment before we were able to recheck the blood tests. In sixty-five cases (57.5 per cent) there was complete or partial reversal of the serologic reactions. In twenty-four cases (21.2 per cent) the serologic reactions remained unchanged.

The Kline diagnostic and exclusion tests and two cholesterinized Wassermann tests were made on all patients. When the Kline reactions were strongly positive (4 plus) the blood specimens were diluted in order to determine the reagin titer, and the results were recorded in units of reagin. Some specimens had a titer of more than 400 units; after a series of mapharsen injections the titer was reduced to 20 units. If the samples of blood had not been recorded, those taken at both times would have been recorded as 4 plus, but according to the titration method there was an evident marked response to therapy.

The therapeutic effect of mapharsen on the cutaneous manifestations of syphilis was striking. In the primary lesions there was rapid sterilization and healing. The patients with active secondary manifestations showed early disappearance of the lesions. Those with gummatous lesions of the skin showed a similar rapid healing.

TABLE 1.—Effect of Mapharsen Therapy on the Serologic Reactions

Serologic Reaction	Number of Cases	Percentage of Cases
Became and remained negative.....	19	16.8
Improved.....	46	40.7
Not improved.....	24	21.2
Test not repeated.....	24	21.2
Total.....	113	

Many patients with cardiovascular and central nervous system syphilis, who had symptoms referable to the affected organs, volunteered the information that a marked improvement or disappearance of disturbing symptoms occurred soon after therapy was begun. Although such subjective symptoms are relatively of little significance, it is nevertheless noteworthy that many patients remarked that they "felt better," "improved in appetite," "gained weight," "slept better," or progressed in other ways.

The prompt healing of cutaneous lesions, the complete or partial reversal of serologic reactions and the improvement of subjective symptoms following mapharsen therapy compare favorably with the response to arsphenamine and neoarsphenamine therapy.

In this series the majority of patients received alternating courses of mapharsen and of bismuth compounds consisting of twelve injections each per course. Others received treatment by the concurrent method—that is, mapharsen each of a bismuth compound and of mapharsen alone—that is, a few were treated with heavy metal.

The clinical and serologic response to mapharsen therapy was much more favorable in patients who were treated by the concurrent method, i. e., a combination of mapharsen and a bismuth compound. An experiment in which we attempted to assess the effect of mapharsen alone in a single patient proved disappointing.

A man aged 37 developed a penile chancre three weeks after exposure. Serologic reactions were doubtful with Wassermann and Kline diagnostic and exclusion tests at the first examina-

tion, but all tests became strongly positive in forty-eight hours. He received intravenous injections of mapharsen daily for sixteen days. The dosage varied from 0.03 to 0.06 Gm. with a total of 0.88 Gm. (0.055 Gm. per injection). Regression of the chancre was very slow and the reduction of the serologic titer was equally retarded. At this juncture, the patient received five intramuscular injections of a bismuth compound and four additional mapharsen injections. Even after the first injection of bismuth a noticeable regression of the chancre was apparent. At the termination of this concurrent series of mapharsen and bismuth injections the chancre had healed completely and Kline diagnostic and Wassermann tests were negative.

This isolated experiment, meager as it is in significance, suggests two things: first, that mapharsen is relatively nontoxic and may even be given daily without producing serious untoward reactions; second, that despite daily administrations of conventional doses, when unsupported by a heavy metal it was not effective.

For two women with secondary syphilis, two methods of treatment illustrating the efficacy of combined therapy were employed. The first patient received three injections a week of mapharsen for a total of thirty-nine injections, with an aggregate dosage of 1.44 Gm. (0.037 Gm. per injection). During this period she received only two intramuscular injections of bismuth. Although the cutaneous eruption disappeared within the first two weeks, the blood tests were still positive at the end of this course. She then received four weekly injections of bismuth, at the end of which there was a marked reduction of the reagin titer. After this she received additional treatment of thirty-one mapharsen injections (1.43 Gm., or 0.046 Gm. per injection) and eight intramuscular bismuth injections, at the end of which all the blood tests were negative, as they have remained to the time of the last examination, i. e., for an interval of sixteen months. Cardiovascular and spinal fluid examinations also were negative. This patient with secondary syphilis therefore required a total of seventy-one injections of mapharsen (2.85 Gm. of mapharsen) and fourteen intramuscular injections of bismuth to produce and maintain a complete serologic reversal.

The second patient with secondary syphilis received one intravenous injection of mapharsen and one intramuscular injection of bismuth concurrently once a week. She received sixteen injections of mapharsen (0.58 Gm., or 0.036 Gm. per injection). At the end of the twelfth injection all tests were completely negative, as they have remained for the past twenty-eight months.

Two men with primary lesions also were compared. The first, aged 29, had a chancre on the chin and positive blood tests. He received three injections of mapharsen and one intramuscular injection of a bismuth compound each week, for a total of twenty-eight injections of mapharsen (1.51 Gm., or 0.054 Gm. per injection). At the end of three weeks the primary lesion was completely healed, but at the conclusion of twenty-eight injections he developed an arsenical eruption simulating pityriasis rosea. Mapharsen was stopped temporarily. On resumption of mapharsen the dermatitis recurred. He then was given eighteen additional weekly injections of bismuth, at the conclusion of which all tests were completely negative; they have remained so to the present time (twenty-one months). The spinal fluid and cardiovascular examinations were also negative.

The other patient, aged 34, presented a penile lesion with a positive dark field examination and positive blood tests. He received three injections of mapharsen on three successive days and then concurrent injections

of mapharsen and bismuth, one of each once a week, for a total of seventeen injections of mapharsen (0.9 Gm., or 0.053 Gm. per injection) and fifteen injections of a bismuth compound. All the blood tests became negative after the fourteenth injection of mapharsen and have remained negative ever since (twenty-three months).

These five cases, although inadequate to permit definite conclusions, at least suggest that:

1. Mapharsen is relatively nontoxic and may be given daily without producing serious untoward reactions.

2. Mapharsen alone in such frequent administrations may produce rapid healing and disappearance of early cutaneous syphilis but does not produce an early serologic reversal.

3. Mapharsen used concurrently with a heavy metal (bismuth) not only produces more rapid healing of early cutaneous lesions but also effects and maintains an early complete reversal of the serologic reactions.

We feel that the more frequent administration of mapharsen (from three to seven injections a week), although well tolerated by patients with normal renal, cardiac and hepatic functions, does not add to the efficacy of treatments as manifested by more rapid sterilization and healing of early cutaneous lesions or by producing and maintaining an early complete serologic reversal.

Massive initial doses of mapharsen did not increase the effectiveness of treatment in early syphilis, a fact already noted by Foerster and his collaborators.⁴

UNTOWARD REACTIONS

The majority of investigators draw attention to the fact that mapharsen is relatively less toxic than the commonly used arsenicals and stress the point that there has not been a single report of hemorrhagic encephalitis or of death attributed to the use of mapharsen. The toxic effects of mapharsen are commonly classified as immediate or delayed reactions. The former group consists of (1) venous spasm, (2) mild gastrointestinal disturbances associated with nausea, vomiting and abdominal pain, (3) headache, (4) weakness or collapse and nitritoid reactions. The delayed reactions include such conditions as (1) nausea and vomiting, (2) fever and chills, (3) dizziness and fainting (4) precordial pain, (5) blood dyscrasias, (6) hemorrhagic encephalitis, (7) urticaria, (8) herpes (simplex and zoster), (9) dermatitis, (10) fixed eruptions, (11) plaquelike eruptions, (12) crustaceous lesions, (13) jaundice, (14) delayed nitritoid reactions, (15) exacerbations of preexisting eruptions, (16) ninth day erythema of Milian, (17) ocular disturbances, (18) renal damage and (19) neuritis.

Venous Spasm.—Early in our experience with mapharsen we noticed that several patients developed pain along the course of a vein due to venous spasm. This occurred during or immediately after the injection, especially if it was administered slowly. Sometimes these pains would extend as high as the shoulder; they would persist from a few minutes to twenty-four hours. When the drug was administered more rapidly, this reaction was eliminated almost entirely. Schoch⁵ has shown that the application of cold wet compresses over the vein is rapidly effective. Perivascular infiltration and extravascular seepage of small amounts of

5. Schoch, A. G.: Treatment of Venous Spasm Resulting from Injection of Mapharsen or Arsphenamine, *Arch. Dermat. & Syph.* 31: 131 (Dec.) 1936.

mapharsen occurred in a few cases. This was associated with a burning pain and followed by a slight local inflammatory reaction but never resulted in local necrosis or sloughing.

Herxheimer Reactions.—Cole and Palmer⁶ reported that the Herxheimer reaction following the use of mapharsen was to be guarded against. They stated that with an initial dose of 30 to 40 mg. this reaction was frequently severe and advised that, in cases in which vital organs are affected by syphilis, extreme caution and a conservative initial dose should be employed. In our experience reactions of this type due to mapharsen were of mild and transitory character. Two patients with secondary syphilis had an exacerbation of the eruption accompanied by a slight elevation of temperature. The initial dose of mapharsen in all our cases was never more than 20 mg. Foerster and Herxheimer⁴ observed similar mild and transitory reactions in their series.

Nitritoid Reactions.—Most clinicians⁷ stress the complete absence of true nitritoid reactions. Swartz⁸ mentioned one specific case and Cole and Palmer⁶ observed four instances of a vascular crisis or a reaction of some sort which closely resembled the nitritoid reaction. In our series we did not encounter a single instance which could be classified as a true nitritoid reaction.

"Ninth Day Erythema."—Milian has called attention to a morbilliform or scarlatiniform eruption which may appear on the ninth day after treatment is instituted. This eruption is self limited, disappearing within three to four days without an aftermath and in spite of continued arsenical treatment. One patient in this series had such an eruption from mapharsen. The following case history is of interest because it is the first recorded instance of ninth day erythema of Milian resulting from the administration of mapharsen:

A man aged 34, first seen on April 9, 1938, had a penile ulcer of twelve days' duration. He was sexually exposed thirty-six days before he noticed the primary sore. Examination revealed a pea-sized indurated ulcer at the urethral orifice and enlarged inguinal lymph nodes. Blood tests were positive. The following treatment was given:

April 11, mapharsen 0.02 Gm. and bismuth salicylate 1.5 cc.

April 13, mapharsen 0.04 Gm.

April 15, mapharsen 0.06 Gm.

April 18, mapharsen 0.06 Gm. and bismuth salicylate 1.5 cc.

April 20, a generalized morbilliform eruption developed, associated with a temperature of 101 F. (nine days after the first injection of mapharsen).

No treatment was given for the rash.

April 22, the eruption had almost completely disappeared. Mapharsen 0.02 Gm. was administered.

April 25, mapharsen 0.04 Gm. and bismuth salicylate 1.5 cc.

April 27, mapharsen 0.04 Gm.

April 29, mapharsen 0.06 Gm.

The patient continued to receive mapharsen and bismuth therapy without having any more untoward reactions. There was no recurrence of the eruption.

Jaundice.—Although jaundice as a complication of mapharsen therapy has been reported, it is not a com-

mon occurrence. Cole and Palmer⁶ reported two cases of jaundice for which mapharsen may have been wholly or partially responsible. In one case the condition was complicated by the presence of malaria; one injection of neoarsphenamine had been given. Foerster⁴ reported that jaundice developed in four cases in his series (5 per cent) after mapharsen therapy. Three patients had received mapharsen only; one had received arsphenamine, mercuric salicylate and bismuth subsalicylate during a period of twelve months and had no treatment during the six months prior to treatment with mapharsen. In our present study, one patient had jaundice after mapharsen therapy:

A man aged 30 had a penile chancre in 1929 and received irregular treatment consisting of seventy injections each of neoarsphenamine and a bismuth compound. From December 1937 to July 1938 he received twenty-four intramuscular injections of bismuth salicylate. On September 7 an initial injection of mapharsen 0.02 Gm. was administered. This was followed by injections of mapharsen at weekly intervals for a total of eight injections (0.35 Gm.). After the third and each subsequent injection some nausea developed, but not of sufficient severity to warrant discontinuance of mapharsen therapy. Eight days after the eighth injection the patient became quite ill. Examination showed mild jaundice associated with an

enlarged tender liver. All antisyphilitic treatment was discontinued and sodium thiosulfate therapy (intravenous and oral) was instituted. He made an uneventful recovery, and the jaundice had completely disappeared in eight weeks.

Aplastic Anemia.—In the numerous reports in the literature dealing with untoward reactions following mapharsen therapy there is not a single recorded instance of aplastic anemia or death which could be attributed to mapharsen. Cole and Palmer⁶ reported one case in which acute nephrosis developed with fatal termination. The patient was a chronic alcoholic addict who tolerated both mapharsen and bismuth therapy without apparent reaction. The pathologist believed it impossible to define the cause of nephrosis and thought it conjectural that the nephrosis was due to mapharsen. In our series one patient developed aplastic anemia which terminated fatally; this is the first recorded death probably due to mapharsen therapy:

A woman aged 30 was referred to us for antisyphilitic therapy. Routine blood tests were strongly positive for syphilis. Physical examination showed no clinical evidence of syphilis. The patient stated, however, that she had been exposed sexually to only one man during the past three years. This contact had positive blood tests and was receiving antisyphilitic therapy. Our patient received four intramuscular injections of an insoluble bismuth preparation at five day intervals, followed by thirteen injections of mapharsen and the same bismuth preparation, one of each once a week. The initial dose of mapharsen was 0.02 Gm. and the total dose 0.36 Gm. (average dose 0.028 Gm.). The patient ate some fish, after which she experienced marked nausea and vomiting. The fol-

lowing morning she developed generalized giant urticaria. She remained nauseated for twenty-four hours after the fourth injection of mapharsen (0.06 Gm.). The fifth injection was reduced to 0.02 Gm. and was followed immediately by the ingestion of 5 drops of compound solution of iodine in a glass of water (in an attempt to prevent nausea). The patient experienced no nausea after the injection. When the dose of mapharsen was increased above 0.02 Gm. the injection was followed by nausea, regardless of whether or not the compound solution of iodine was administered. At no time was it felt that the nausea was of sufficient severity to warrant the discontinuance of mapharsen. Following this first course of treatment (thirteen injections of mapharsen and seventeen of a bismuth compound) there was a marked reduction of the serologic titer. The patient then received twelve more injections of bismuth at weekly intervals (the last given on Jan. 19, 1938). On January 26 she received an injection of mapharsen (0.02 Gm.), which was followed by slight nausea but no vomiting. One week later a second injection of mapharsen (0.02 Gm.) was given, followed again by nausea but no vomiting. When she returned the following week for her third injection

she was very pale and complained of marked weakness, dizziness and faintness. The hemoglobin determination on that day was 30 per cent.

Immediate hospitalization was advised but the patient did not enter the Metropolitan Hospital, Welfare Island,⁹ until forty-eight hours later (February 11), at which time she submitted the aforementioned history of antisyphilitic treatment. She stated that during the Christmas holidays of 1937 she had influenza which lasted for one week and that since that time she had never felt entirely well, always feeling tired and easily fatigued but with no other specific complaints. One month before she noted "black and blue" spots which appeared on different parts of the body without relation to trauma. She became progressively weaker, and several days before admission she became noticeably pale. Five days prior to admission her weakness became so profound that she was unable to carry on her occupation as a school teacher. She complained of a slight elevation of temperature and of nausea but not of vomiting. Her last menstrual period began on Dec. 15, 1937, lasting the usual length of time with the normal amount of flow. Her next period was due during the middle of January, at which time she had her usual premonitory signs but no bleeding. There was no history of rectal bleeding, hematemesis, sore mouth, burning tongue or difficulty in walking. Dyspnea on exertion had been present for weeks before admission, and there had been a loss of 5 pounds (2 Kg.) in weight.

The patient was well developed and well nourished. She showed profound pallor but did not appear acutely ill. Observations were negative with the following exceptions: The

blood pressure was 85 systolic, 60 diastolic; the lower extremities showed several purpuric areas, and the axillary lymph nodes on the left were slightly enlarged.

During the first two weeks in the hospital the patient improved, with multiple transfusions as the chief form of therapy. During her stay at the hospital she received nine transfusions, as follows: February 12 300 cc., February 14 300 cc., February 16 250 cc., February 18 250 cc., February 20 250 cc., March 3 300 cc., March 7 250 cc., March 10 250 cc., and March 11 125 cc. On February 13 several ecchymotic areas developed on the right leg. On February 16 menstruation began and lasted for four days with normal flow. On March 2, after two intramuscular injections of liver extract, an abscess of the buttock developed. The symptoms noted on admission reappeared (weakness, lassitude). On March 6 the temperature rose to 105.2 F. and from then on until death it persistently rose to about this level. On February 6 pain developed in the right lower quadrant of the abdomen and soon after in the left lower quadrant. The pain was accompanied by tenderness in these areas but there was no rigidity. A surgical consultant decided that the abdomen was not involved in a discernible disease process. On March 10 the patient developed difficulty in hearing and had blurring of vision. A spinal tap done at that time disclosed clear fluid under normal pressure. On March 11 the patient died.

Roentgenograms of the chest and abdomen were negative. Electrophoresis, blood cultures, agglutination tests and sputum and stool examinations were also negative.

Autopsy was performed on March 11. The anatomic diagnoses were as follows:

1. Aplastic anemia due to arsenic treatment for syphilis.
2. Multiple petechial and ecchymotic hemorrhages of the arachnoid, visceral pleura, epicardium, myocardium, endocardium, renal capsules, ileum and cecum.
3. Toxic hepatitis.
4. Bilateral ovarian hemorrhagic cysts.
5. Hyperplastic splenitis.
6. Sanguineous peritoneal fluid (small amount).

Although this is the first reported case of the development of a blood dyscrasia with a fatal outcome following the use of mapharsen, it is interesting to note that Goldberg¹⁰ reported a syphilitic pregnancy in which mapharsen prevented congenital syphilis and at the same time did not cause a recurrence of a serious hemopoietic complication (granulocytopenia), which had occurred after treatment with another arsenical.

COMMENT

The majority of the patients in this series tolerated the mapharsen therapy well and presented no serious untoward reactions, except for those described. Among the 113 patients, who received altogether 2,342 injections of mapharsen, sixteen had mild gastrointestinal reactions (nausea), eleven had nausea and vomiting, four complained of mild headaches and attacks of dizziness, three had pruritus, and one developed herpes simplex. Of these 113 patients, ten had similar reactions with other arsenical preparations, such as neoarsphenamine, silver arsphenamine and arsphenamine. Fifteen patients developed the more serious delayed reactions; two had chills and fever; four developed generalized erythematous eruptions; five had an exacerbation of a preexisting dermatitis (three with seborrheic dermatitis and two with a discoid vesicular dermatitis); two developed fixed eruptions; one complained of precordial pain, and one developed albuminuria.

Mapharsen had to be discontinued for a short time in some of these cases. In three cases the drug had to be stopped entirely because of the recurrence of untoward reactions. In thirteen cases there was no recurrence

9. Drs. Lynn J. Boyd and Van Alstyne Cornell, of the Metropolitan Hospital, gave permission to use the data obtained while the patient was in the hospital.

10. Goldberg, Mortimer: Mapharsen as a Substitute for Neoarsphenamine in Agranulocytic Angina Following Neoarsphenamine Therapy in a Pregnant Syphilitic Woman, *Am. J. Syph., Gonorr. & Ven. Dis.* 23: 79 (Jan.) 1939.

of the reactions when mapharsen therapy was resumed at a reduced or a similar dosage. For two patients treated by Dr. Girsch D. Astrachan (one with nausea, vomiting and fever and the other with headaches, vomiting and fever) the recurrence of these reactions was prevented by the intramuscular injection of liver extract from fifteen to thirty minutes prior to the injections of mapharsen, as advocated by him in a recent publication.¹¹ We were not able to prevent the recurrence of reactions by the oral administration of compound solution of iodine prior to the mapharsen injection.

Some patients had a variety of untoward reactions with the various arsenicals in the course of previous antisyphilitic therapy but did not develop a recurrence of these reactions when they received mapharsen. In this group there were twenty patients with the following reactions: Five had nitritoid reactions, eight had nausea and vomiting sometimes associated with fever, chills, headaches or attacks of dizziness, three had arsenical dermatitis, one had urticaria, and one had angioneurotic edema of the face and hands.

CONCLUSIONS

1. Mapharsen is adequate to control early infectious rapid sterilization of active reactions.
2. The majority of syphilitic patients treated by the physician in private practice are in the latent asymptomatic stage. Mapharsen, possessing relatively lower toxicity, is preferable in such cases to other drugs, which have a greater tendency to produce untoward reactions.

580 Fifth Avenue—200 West Fifty-Ninth Street.

ABSTRACT OF DISCUSSION

DR. GIRSCH D. ASTRACHAN, New York: The main value of this paper lies in the publication of a fatality which could be attributed to the use of mapharsen. This report should draw the attention of physicians to the potential dangers of mapharsen and make them weigh carefully all the necessary indications and contraindications. Dr. Wise and I came to the conclusion some time ago that mapharsen should be preferred in late latent syphilis. Mapharsen is useful also in cases of late congenital syphilis, cases of cardiovascular syphilis and cases in which drastic energetic therapy is not desirable. As a result of a recent study on a limited number of cases (twenty-four) I gained the impression that mapharsen is as efficient as neoarsphenamine in cases of syphilis and pregnancy. Mapharsen has a well deserved place among the efficient antisyphilitic remedies but, regardless of its lower toxicity, it is a powerful arsenical and may be very harmful if used without caution. This factor is being ignored by some physicians, who in their enthusiasm begin to use mapharsen in cases in which sensitiveness possibly exists to the arsphenamines, or in which the arsphenamines are contraindicated. A case is reported in which granulocytopenia developed after the administration of neoarsphenamine and soon after mapharsen was administered. Although this patient benefited greatly from mapharsen therapy, I believe that no trivalent arsenicals should be used again in cases in which there is a history of a blood dyscrasia. I am also against the use of mapharsen (especially in maximum doses) in cases of advanced tuberculosis. Because of several reports of severe complications following the continuation of arsphenamine therapy in cases of ninth day erythema, I believe that as a matter of safety such cases should be regarded as average cases of sensitivity to arsenicals. Only after a blood count and liver function and urine tests are found to be normal should the arsenical be renewed cautiously, beginning with small doses. A blood count was done in most of our cases before mapharsen therapy was instituted and was repeated at the completion of a course of

treatment. This procedure helped to discover signs of beginning dyscrasia of the hemopoietic system before clinical manifestations appeared. I agree with the authors that the efficacy of mapharsen is greatly increased when it is given together with injections of bismuth compounds.

DR. H. M. ROBINSON, Baltimore: It is my impression, after seven years' experience with mapharsen, that it is an adequate antisyphilitic agent. Furthermore, mapharsen is almost the equal of arsphenamine and is superior to neoarsphenamine. Nevertheless I am convinced that none of the generally accepted antisyphilitic drugs need be discarded from our armamentarium. Each drug seems to have some place in our scheme of therapy. In general, I believe that physicians should bear in mind the fact that any of the reactions caused by the trivalent arsenicals can also be caused by mapharsen. Also the patient should be warned beforehand of the local, painful vein reactions. With these provisos I think the drug would be preferable in an office as well as in a clinic. The spirochetes are killed in from six to seven hours by both arsphenamine and mapharsen. It takes somewhat longer for neoarsphenamine to accomplish this result. As for serologic reversal, the work of Moore and his co-workers showed that the serologic reversal is about equal with neoarsphenamine, mapharsen, silver arsphenamine and bismarsen, and that arsphenamine caused a slightly quicker reversal to negative. Several of our patients developed jaundice resulting from mapharsen, a few of them quite serious. There have been two cases of exfoliative dermatitis. However, we have encountered several cases of mild exfoliative dermatitis due to arsphenamine in which the patients could tolerate mapharsen. Sometimes it is important to be able to continue with an arsenical in the treatment of syphilis, especially in pregnancies and in early syphilis, and it is my conviction that mapharsen should be tried before all arsenicals are excluded from consideration. Knowing that many practitioners and specialists are careless about the preparation of the arsenicals, mapharsen comes nearer being a foolproof arsenical than the arsphenamines. You can stir it as much as you want to within reason. In fact, it is advisable to stir it thoroughly in order to liberate the carbonate. If you agitate the arsphenamines too strongly they become toxic. I think mapharsen will probably supersede neoarsphenamine as a drug of general usage, but not entirely, because there are still some patients who cannot tolerate mapharsen but can tolerate neoarsphenamine. Therefore, neoarsphenamine should not be discarded but held in reserve.

DR. WILLIAM BECKER, Chicago: I was gratified to hear the authors and Dr. Astrachan give their preference for the concurrent method of treatment, because we have used that for many years in our clinic. We have always thought that it had advantages over the alternating system of therapy and we have not experienced any increase in reactions from its use. In mapharsen one has what is probably the active drug that is liberated by arsphenamine in the body. Chemical methods as yet are inadequate, so that we do not know how much arsenoxide is liberated over a certain period of time from one of the arsphenamines. It may even be that if mapharsen was given in small doses, several times daily, we would be approaching the optimal method of administration. I have always been favorably inclined toward the use of bismuth. Levaditi and certain French workers found that they could almost, but not quite, cure syphilis with bismuth. Our treatment system is incorporated on that principle; that is, we use a lot of bismuth and not a great deal of arsenical. When a patient comes with an early lesion, primary or secondary, instead of starting out with a long series of arsenical injections we give bismuth right from the start. We give the patient a small dose of mapharsen, along with a small dose of soluble bismuth. This is repeated two days later and again two days after that, after which we give it once every five days or once weekly. I believe that this combination therapy will have the advantage of preventing the appearance of the so-called refractile cases. In other words, if one starts out with a long series of arsenical injections, one may find that pretty soon the lesions instead of becoming better will become worse, but if you give bismuth right from the start I think that this relapse will probably be prevented. I believe that a great deal of bismuth and not so much mapharsen given by the concurrent method is an extremely good method for the practitioner and is safer than the other methods.

11. Astrachan, G. D.: The Value of Administration of Liver in Patients Intolerant to Arsenicals, *J. Invest. Dermat.* 1: 427 (Dec.) 1938.

DR. LEON GOLDMAN, Cincinnati: In Cincinnati recently there was a fatal case from mapharsen and this report is from the Chronic Disease Hospital and is by several men in the medical service there. The case will appear shortly in the literature. A middle aged man developed hematuria and then renal insufficiency following mapharsen. To compensate for this somewhat, at this hospital we have been conducting a study purely for academic purposes on the effect of mapharsen on late and latent syphilis in patients who are 70 and 80 years old.

DR. CHARLES R. REIN, New York: Although a number of the patients in this series showed a satisfactory serologic response following mapharsen therapy, the incidence was not as high as should be expected if a similar number of patients with early syphilis were treated with the same preparation. In our series the majority of patients had their infections for many years and received an average maximum of only twenty injections per patient. Dr. Sharp, of Detroit, was kind enough to review our report and made the following note regarding the fatality which occurred during mapharsen therapy: "The development of anemia, leukopenia accompanied by neutropenia and thrombocytopenia in the patient receiving antisyphilitic therapy are presumptive signs of chemical toxemia. Inasmuch as similar hemopoietic patterns do occur frequently in nonsyphilitic patients not having received any drugs within a reasonable period of time prior to acute hematologic manifestations, unknown etiologic factors cannot be excluded from consideration. I do not recall how many similar cases I have studied, but the clinical picture is not uncommon and infection of a degree ordinarily regarded as inconsequential occasionally is the only discernible pathogenesis." It is quite possible that the blood dyscrasia in this patient may have been due to something other than the mapharsen. Mapharsen should be used with a great deal of discretion. If administered indiscriminately it may produce serious untoward reactions.

SURGICAL LESIONS OF THE PARATRIGEMINAL AREA

LOYAL DAVIS, M.D.

AND

JOHN MARTIN, M.D.

CHICAGO

In 1923, one of us¹ called attention to the clinical syndrome produced by lesions of the paratrigenal area. In this small anatomic space are located the sensory and motor roots of the fifth cranial nerve, the gasserian ganglion and its three branches, the carotid artery and the plexus of the sympathetic nerve fibers which surround it, and the oculomotor, trochlear and abducens nerves which innervate the extra-ocular muscles (fig. 1). Obviously, with all these important structures crowded into a small area the potentialities of many symptoms from even a very small lesion are great.

In one of our two cases reported at that time there were excruciating pain in that area of the right side of the face supplied by the ophthalmic and maxillary divisions of the trigeminal nerve and paralysis of the sympathetic nerve fibers innervating the eyeball, as evidenced by a small pupil which failed to dilate after the introduction of cocaine solution, a narrowed palpebral fissure due to an enophthalmos and an absence of the ciliospinal reflex. Autopsy disclosed a small aneurysm of the internal carotid artery. A second patient also suffered with pain of a similar excruciating character but distributed in the area supplied by all three

divisions of the left trigeminal nerve. She presented ptosis of the left upper eyelid, dilatation of the pupil and paralysis of all the extra-ocular muscles supplied by the left oculomotor nerve. This patient, too, proved to have an aneurysm of the internal carotid artery at autopsy. The third case included in the original report had been cited by Raeder² in 1918. In common with

Fig. 1.—Anatomic relations in the paratrigenal area.

our cases there had been severe pain on one side of the face in the area supplied by the trigeminal nerve. A small pupil, enophthalmos and paralysis of the muscles supplied by the motor division of the trigeminal nerve completed the clinical symptoms. Raeder stated that at autopsy a small "endothelioma" was found originating from the medial edge of the gasserian ganglion.

During the past sixteen years fourteen other cases have been observed in which the symptoms may be classified as belonging to this syndrome. In six instances the lesion was verified as an aneurysm of the internal carotid artery either at autopsy or at operation; in seven cases a small meningioma, wholly confined to the dural envelop which encloses the gasserian ganglion, was removed at operation and verified microscopically and in the one remaining case neither an aneurysm nor a tumor could be verified at operation, although following the surgical exposure of the paratrigenal area the symptoms have subsequently all disappeared.

Attention is again called to the lesions which occur in this area not only because of the interesting clinical syndrome which is presented in any one of several combinations of symptoms but because (1) the symptoms must be differentiated from those which occur in cases of major trigeminal neuralgia, the etiology of which is as yet unknown, and (2) because the symptoms of one half of the patients in this group have been relieved by operation.

Without exception, all these patients presented themselves for relief of the severe pain which they suffered in the area of distribution of the trigeminal nerve. Failure to obtain relief from this persistent excruciating pain by the usual analgesic drugs or by alcohol injections had led them, directly or by reference, to seek surgical attention. This pain is one of the first symptoms noted by the patient and in our experience has occurred in one, two or all branches of the gasserian ganglion, but without fail the ophthalmic division has always been involved. A trigger zone, so pathognomonic of trigeminal neuralgia, may or may not be present.

From the Division of Surgery, Northwestern University Medical School.

Read before the Section on Surgery, General and Abdominal, at the Nineteenth Annual Session of the American Medical Association, St. Louis, June 17, 1939.

¹ L. Davis, Loyal E.: Lesions of the Paratrigenal Area. *J. A. M. A.* 80:380 (Feb. 10) 1923.

² Raeder, G.: Report of a Case of Endothelioma in the Paratrigenal Area. *Norsk. mag. f. lægevidensk.* 79, 1918.

Though sharp and severe the pain seldom has had the paroxysmal character of true trigeminal neuralgia, nor is it as shocking and terrifying to the patient. Often the pain seems to radiate peripherally from an origin located indefinitely by the patient as "somewhere behind the eye." Several patients have complained of a severe, dull headache localized to a point deep within the anterior portion of the cranium on the affected side.

Without exception we have found that when this syndrome has been due to a small meningioma, originating within the dural envelop which encloses the gasserian ganglion, there have been small patchy areas of paresthesia, numbness and even complete loss of sensation to pin prick and touch stimuli in the ophthalmic and maxillary areas of the face on the side of the lesion. This is so constant an occurrence, if examined for carefully and meticulously, that we have come to regard it as pathognomonic of the presence of such a tumor. Raeder did not comment on a loss of sensation by his patient who had an "endothelioma," which we assume is the term commonly in use twenty years ago for this same type of tumor. Involvement of the motor division of the trigeminal nerve, as noted by Raeder in his case, was also present in two of our cases (both with tumors) but the paralysis of the pterygoid and masseter muscles was only partial.

Accompanying these symptoms of involvement of the trigeminal nerve have been the signs produced by involvement of the third, fourth and sixth cranial nerves, which innervate the extra-ocular muscles. As might be expected, these nerves may be affected singly or in any possible combination. The most common manifestations have been those which pointed to the oculomotor nerve and have been characterized by a dilated pupil, an actual ptosis of the upper eyelid and divergence of

the eyeball to the outer canthus. In two cases, in which there was a meningioma, there was a complete paralysis of the external rectus muscle, pointing to a lesion of the abducens nerve, and in another case, in which there was a large aneurysm of the internal carotid artery, a complete ophthalmoplegia was present. In no instance in which a meningioma was found and removed at operation have the extra-ocular muscles failed to recover their function. In fact, the marked ocular

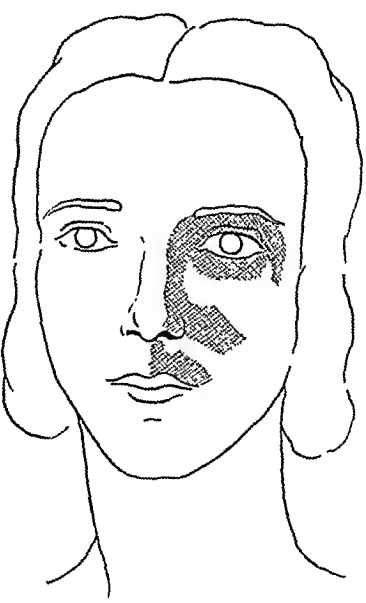

Fig. 2.—Loss of sensation in the face caused by meningioma in the paratrigenal area.

symptoms have been more characteristic of the cases in which there were aneurysms of the internal carotid artery.

When the sympathetic nerve fibers which surround the carotid artery and accompany the ophthalmic division of the trigeminal nerve are involved, a typical Horner's syndrome is produced with enophthalmos, a narrowed palpebral fissure and a small pupil which will

fail to dilate after the introduction of cocaine solution. Under these circumstances, which most often occur with aneurysms of the internal carotid artery, the ciliospinal reflex is also absent.

That surgical help can be given to at least one half of these patients in our experience and that a shrewd guess can be made that a small meningioma rather than

Fig. 3.—Low power section showing characteristic microscopic appearance of the meningiomas found in the paratrigenal area.

an aneurysm is present and that these patients come to the surgeon for relief of the severe pain in the face is illustrated by the following case:

A woman aged 50 first complained of a jabbing, knifelike pain in the left eye in June 1937. This was not present constantly but came in attacks and soon involved the left frontal and the left maxillary areas. Cold air, rubbing the left temporal area or touching the site of the removed left canine tooth brought on the pain. At frequent intervals diplopia would be present for hours or days at a time.

On examination, stimulation of the zones described by the patient produced a sharp increase in her pain but it was obvious that she was never entirely free from a pain described as "deep in the left eye." No impairment of the extra-ocular muscle movements could be elicited on examination. There was a loss of sensation to light touch and pin prick stimuli over the left upper lip, left ala and left side of the nose which extended laterally about 2 cm. The left upper and lower eyelids were also insensitive (fig. 2).

At operation the gasserian ganglion enclosed in its dural envelop appeared coarse, large and red. When the envelop was opened a purple soft mass was found occupying the site of the ganglion and wholly enclosed within its dural envelop. The mass was removed completely and the sensory root divided.

The patient has had no recurrence of her pain, and no new symptoms have developed during the past year following her operation.

This story is quite typical in the six other cases in which a tumor in the same location, with the same gross appearance and with the microscopic characteristics of a meningioma, has been removed. In each instance

there has been severe pain in the trigeminal area and except for the last three cases an operation was devised for the relief of trigeminal neuralgia. The presence of small, scattered areas of sensory loss in the trigeminal area on the side of the pain has led us to the correct diagnosis in the last three cases.

These tumors are not tumors of the gasserian ganglion and show none of the microscopic characteristics of such tumors, which are not uncommonly found.

Fig. 4.—High power section showing characteristic microscopic appearance of the meningiomas found in the paratrigenal area.

As is shown in figures 3 and 4, the tumor tissue is composed of a uniform epithelioid type of cells with central round, granular or reticular nuclei, which are arranged in poorly defined whorls about central blood vessels. Other more elongated endothelial-like cells are present and mitoses are fairly common.

These are not the large tumors which Cushing has described in his monograph "The Meningiomas" as "sitting like a saddle astride the anterior end of the petrous ridge." That, if allowed to go unrecognized for any length of time, they would eventually grow to extend into the middle and posterior fossae of the skull is quite probable. However, in these seven instances the severity of the pain has forced early surgical intervention and as yet we have seen no evidences of recurrence of the tumor though the first operation was performed eleven years ago.

The story of the patients with an aneurysm which produced paratrigenal symptoms and signs is not a happy one, but in view of the potentialities of the lesion it may be of much longer duration than one would at first imagine:

A woman aged 47 had a severe pain in the right eye followed by a terrific generalized headache while attending a funeral in 1932. Her vision was dim and she had a diplopia. The headache, present since the onset, was described as a sharp, continuous pain over the right temporal area which varied in intensity. This pain seemed to "shoot through" the right eye in attacks and when this occurred, as it did about once a week, she became nauseated, vomited and had a true vertigo. A

"boiling, drawing" pain had been present over the vertex of the skull since 1934. Although she had diplopia from the onset, she did not notice that her right eye was turning to the left and that the pupil was large until a year later.

In 1937 it was noted that the right upper eyelid was "drooping" and she could not open her eye easily. Simultaneously a tingling, fiery, sharp pain occurred frequently in the right side of the face and would last about fifteen minutes, to be followed by numbness in the right side of the tongue, the teeth and gums on the right side.

There was a definite ptosis of the right upper eyelid, and the right pupil was larger than the left and reacted sluggishly to light. The visual fields and acuity were normal in both eyes. In looking upward and to the left and right, the right eye did not move at all but did move on looking down (fig. 5). There was diminution to pin prick and touch stimuli over the right maxillary area and on the right side of the tongue.

At operation an enormous aneurysm of the internal carotid artery extended upward and laterally into the middle fossa.

Although it has been assumed that the majority of such intracranial aneurysms are the result of syphilis, the serologic reaction of this patient and the other five patients has been negative. Seven years since the onset of her first symptoms and one year since operation, the patient continues with her household affairs with frequent attacks of pain which incapacitate her.

In 1937 Dandy³ reported a case in which there was an intracranial aneurysm of the internal carotid artery. He operated and was able to put a silver clip on the neck of the aneurysm. The symptoms were very similar to those we have found in our cases. As Dandy properly remarks, one cannot be sure that even after an aneurysm is disclosed at operation it will prove to be amenable to surgical attack. As in our case just cited, the aneurysm was far too large for one to be able to disclose the point of its origin. On the other hand,

Fig. 5.—Appearance of patient with an aneurysm of the internal carotid artery, showing ptosis of the pupil and ophthalmoplegia.

Dandy's report is of considerable interest because if these cases can be diagnosed early enough and the aneurysm is small, the situation is not entirely hopeless.

Extensive paralysis of the extra-ocular muscles has been quite characteristic of the cases of aneurysm of the internal carotid artery and in our experience the oculomotor nerve has been more constantly involved than the

3. Dandy, Walter E.: Intracranial Aneurysm of the Internal Carotid Artery, *Tr. South. S. A.* 50: 14, 1937.

other nerves to the extra-ocular muscles. With respect to the pain, it is our opinion that in the cases in which there is an aneurysm the character and distribution of the pain does not resemble the pain of trigeminal neuralgia as closely as it does in the cases in which there are meningiomas of the dural envelop of the ganglion. Neither have we found the presence of a sensory loss as constant in the instances of aneurysm.

SUMMARY

A group of patients who seek relief from severe, excruciating pain located in the distribution of the trigeminal nerve also present symptoms pointing to involvement of the other structures located in the paratrigeminal area. Paresis or paralysis of the extra-ocular muscles or intrinsic muscles of the eye should direct attention to the possibility of a lesion in this area. Small tumors confined within the dural envelop of the gasserian ganglion verified as meningiomas and aneurysms of the internal carotid artery have been encountered in sixteen cases in which there were various combinations of symptoms characteristic of a pathologic condition in the paratrigeminal area. The prognosis in the cases of intracranial aneurysm has been uniformly poor but on the contrary in each instance the tumors found have been removed successfully.

54 East Erie Street.

ABSTRACT OF DISCUSSION

DR. ERNEST SACHS, St. Louis: This paper deserves a great deal of attention because the differential diagnosis comes up not infrequently between a true tic douloureux and pain in the face due to a tumor in the region of the gasserian ganglion. I operated in a case of this sort in 1915 and at that time I attempted to differentiate between the symptoms of true tic douloureux and tumors arising in this region. One of the points that I feel is particularly important is that whereas in true tic douloureux the patient has intermittent attacks of pain, in this disease it is constant. That is one of the important early differential points; and the other is that the motor root of the fifth nerve is involved; whereas in true tic douloureux I have never seen involvement of the motor root. When I operated in this case I was under the impression that I was dealing with an endothelioma. The patient, however, had a recurrence after one year and died. I did not attempt to reoperate on her. I believe that this should properly be called a malignant tumor. The six cases of Dr. Davis were aneurysms, meningiomas and benign tumors. As a rule, they are benign, and I have recently had two cases similar to the ones he has described, but in neither of them were the third, fourth and sixth nerves involved. I believe that it may be possible to diagnose this condition at an earlier stage if one is so fortunate as to see them early, the important differential point being that in this condition the pain is constant and there is involvement of the motor root, which is not found in trigeminal neuralgia. In one of my cases the meningioma lay on the posterior root of the ganglion and was so small that it had not yet pressed on any of the neighboring nerves. This is unusual; as a rule the meningioma is larger and involves some other nerves, as in Dr. Davis's cases.

A Method Imperfectly Understood.—The healthiest trend of modern medicine—and let it be said at once that it is a trend which is anything but universal—is to dispense as far as possible with special methods of investigation in dealing with the everyday patient. The special method is for the investigator into pathological processes; it is not for the pure clinician. The use of special devices, of special tests, almost always leads one way: the devices and tests are employed by men who cannot have the training, cannot afford the time fully to understand, and a method imperfectly understood is, generally speaking, worse than useless.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

CONTACT DERMATITIS FROM OPIUM DERIVATIVES

WITH SPECIAL REFERENCE TO OCCUPATIONAL ASPECTS

JAMES W. JORDON, M.D.

AND

EARL D. OSBORNE, M.D.

BUFFALO

Drug eruptions from the ingestion of or parenteral use of morphine, codeine and other opium derivatives are well known to dermatologists. Most American authors of textbooks on dermatology include opium and its derivatives as a cause of drug eruptions. Scheer and Keil¹ in 1934 called attention to codeine as a cause of dermatitis medicamentosa. Touraine² in 1936 exhaustively described drug eruptions from opium compounds. Many morphologic types of eruption have been produced by the ingestion of or parenteral use of opium compounds. The most common are urticarial, morbilliform or scarlatiniform, but eczematous eruptions in which the chief allergic response is at the same site as in contact dermatitis have been described. Thus opium compounds are capable of producing not only an urticarial and scarlatiniform eruption but also an eczematous response when taken internally by ingestion or injection.

Eczematous dermatitis from opium compounds used externally in the form of lotions, suppositories and the like has been recorded in the foreign literature for many years. Touraine² thoroughly reviewed this literature and stated that Comanus reported the first case in 1882. Since then Bodin in 1901 and Bourges in the same year recorded similar observations. To our knowledge two analogous cases have been reported in the American literature. In one of these, reported by Heller in 1931,³ lead and opium wash was applied externally to the genital area. This resulted in a severe eczematous dermatitis. In the second case, reported by Cumber,⁴ also in 1931, ethylmorphine hydrochloride had been used in the eye with resulting dermatitis of the lids.

Reports of occupational dermatitis due to opium and opium derivatives have appeared sporadically in the European literature. Touton,⁵ in Jadassohn's Handbook, recorded six cases. Pignot⁶ reported eighteen such cases at the sixth International Congress of Industrial Diseases. Touraine and Scémama⁷ reported a case in 1936. Cranston Low,⁸ in his book *Anaphylaxis and Sensitization*, stated that dermatitis from opium compounds is commonly seen in workers engaged in the manufacture of these drugs. We have been unable to find a report of occupational dermatitis due to morphine

or other opium derivatives in the American literature. Likewise we have been unable to find any record of occupational dermatitis in nurses, pharmacists, physicians or other workers who come in contact with these substances in the course of their professional duties. Our discovery of three such cases in nurses and one in a young woman who was employed in the manufacture of morphine tablets has prompted us to present this subject. We believe that opium and its compounds may be an important though unrecognized cause of dermatitis in nurses, physicians, pharmacists and workers engaged in the manufacture and handling of these compounds.

Opium contains two chief classes of alkaloids:⁹ benzyliso-quinolene derivatives, of which papaverine and narceine are examples, and phenanthrene derivatives, of which morphine, codeine and cibane are natural alkaloids and from which synthetic compounds are manufactured, such as ethylmorphine hydrochloride; apomorphine, a dehydrated morphine compound; heroin, or diacetylmorphine, and many others. Most cases of contact dermatitis that have been proved to be due to opium compounds have been due to the phenanthrene derivatives. For example, Lewin⁵ reported a case due to apomorphine. Low believes that codeine is the most common cause. Pignot's eighteen cases occurred among workers with morphine, codeine and heroin. He noted dermatitis most commonly in workers engaged in the purification of diacetylmorphine or heroin and its hydrochloride. Touraine and Scémama obtained positive intradermal tests to both narceine, a benzyliso-quinolene derivative, and codeine, a phenanthrene derivative. However, the results of intradermal tests are of little value since, as Pilcher and Sollmann¹⁰ have shown, most normal persons have a positive intradermal reaction to morphine.

REPORT OF CASES

CASE 1.—E. B., a student nurse aged 21, was first seen in 1930, at which time she complained of an eruption of one week's duration on the third and fourth fingers of the left hand. The eruption was confluent and papulovesicular and was accompanied by considerable itching. The condition was tentatively considered to be ringworm but no proof was established. The eruption partially subsided at the end of a week; three weeks later it recurred in greater severity on the hands. She was advised to discontinue work and at the end of a week was much improved. The condition at this time was considered plant dermatitis. Three weeks after the patient's return to work a new attack of dermatitis appeared on the hands and face, with marked swelling of the eyelids. At the end of a week the dermatitis on the face subsided, but the eruption on the hands persisted. During the next month she continued to have slight exacerbations, with periods of quiescence. She was patch tested to all the plants with which she came in contact in the wards, with negative results. One month later she had another severe outbreak and she was tested to chloroform, solution of formaldehyde, grain alcohol and rubbing alcohol, all reactions being negative. She continued to have exacerbations and periods of relative quiescence during the next two years. We then patch tested her to morphine in dilutions of 1:100, 1:1,000, 1:10,000, 1:100,000 and 1:1,000,000. She showed a strongly positive eczematous response to all these dilutions. She was then tested to apomorphine, papaverine, ethylmorphine hydrochloride and codeine, all in a dilution of 1:1,000. With this

dilution the reactions were moderately positive to apomorphine, papaverine and ethylmorphine hydrochloride but not as strongly positive as they had been to morphine 1:1,000,000. Codeine gave negative results. At one time the patient was away from work for one year, during which time she had no recurrence of the dermatitis. It promptly recurred when she returned to her regular duties. She was therefore transferred to the outpatient clinic in dermatology and had no dermatitis during the week, but after week ends, when she was required to perform relief duties in the wards, each Monday she reported a mild recurrence in spite of the fact that she did not actually, to her knowledge, come in contact with opium or its derivatives. The problem was solved by having her work in the x-ray department, where no morphine or other opium derivatives were used. Subsequent observations showed that the air of the general ward where morphine was used produced itching and burning of the exposed skin when she was in the room for a few minutes. Attempts at desensitization, using baths of morphine sulfate in dilutions greater than 1:1,000,000,000, produced general erythema and had to be abandoned.

CASE 2.—F. A., a student nurse aged 20, first developed an eruption on the hands in July 1934. At this time she had been in training for about a year and was working in the surgical clinic. She applied fungorex, a proprietary remedy, and the eruption disappeared. She then went to work in the hospital diet kitchen and two days later the eruption recurred. She was first seen on August 4, at which time she had a confluent erythematous vesicular dermatitis about the nails of both hands and a few lesions on the palms and backs of the hands. She was patch tested to the soap she was using and to solution of formaldehyde U. S. P. diluted 1 to 400. Reaction to the former was negative but the formaldehyde gave a strong positive reaction. During the next four months she continued to have recurrences in spite of the fact that she was not exposed to formaldehyde. She was not seen again until November 1936, at which time she had a papulovesicular eruption involving the fingers and dorsum of the hands, which had been present for several months. She gave no history of contact with formaldehyde. Two months prior to the visit in 1936 she had taken a codeine tablet and the next day had a generalized eruption. This disappeared in a few days. She was patch tested to codeine 1:100 and morphine 1:100. Both tests were strongly positive. During the past four years she had noted that each time she handled a morphine tablet the dermatitis recurred. She had no recurrences when she was not exposed to morphine.

CASE 3.—V. M., a student nurse aged 19, when first seen in January 1937 had a discrete deep-seated vesicular eruption involving the left palm and wrist, with an area of confluent scaling dermatitis at the base of the right fourth finger. This eruption had been present approximately ten days. At this time she had been in training about a year and a half. Mycotic infection was suspected and under treatment the eruption disappeared. During this period she was working in the diet kitchen. In December 1937 a severe recurrence developed while she was working in the surgical ward. Patch tests were applied with 1:100 dilutions of mercury bichloride, atropine sulfate, procaine hydrochloride, morphine sulfate, papaverine and codeine, and with thymol iodide powder, saturated solution of boric acid, 5 per cent boric acid ointment, zinc oxide, face powder, dusting powder, hand lotion, alcohol, three different soaps, tincture of benzoin and theobroma oil, all of which she handled in the course of her work. There was a strongly positive reaction to morphine and papaverine and a weakly positive reaction to codeine. During the next week she carefully avoided morphine and other opiates, and the dermatitis disappeared. She then was required to take care of a patient receiving morphine injections and developed another severe recurrence on her hands. Because of the dermatitis she discontinued training. The dermatitis did not completely disappear for several months. She had no recurrence for one and a half years. During this interval she did not come in contact with morphine. She then gave one hypodermic injection of morphine to a patient and the next day an acute vesicular dermatitis appeared on the

9. Small, L. F.: *Chemistry of the Opium Alkaloids*, Supplement 103 to Public Health Reports, U. S. P. H. S., 1932. Sollmann, Torald: *A Manual of Pharmacology*, ed. 5, Philadelphia, W. B. Saunders Company, 1937, p. 273.

10. Pilcher, J. D., and Sollmann, Torald: *Skin Reaction to Morphine*, Arch. Int. Med. 33: 516 (April) 1924.

hands, accompanied by erythema and edema of the face. She had used precautions to avoid direct contact with the morphine tablet.

CASE 4.—F. G., a woman aged 48, a medicinal tablet molder, first seen in October 1938, had worked ten weeks molding morphine and strychnine tablets for a drug company. Three weeks after she began this work an eruption appeared on the flexor surface of the arms, particularly about the antecubital areas. The eruption spread to the back of the neck, the hands and the eyelids. In the course of her occupation she came in contact with powdered morphine and powdered strychnine. She continued with her work for three weeks after the first appearance of the dermatitis, during which time the eruption became more severe. She discontinued work on August 24, approximately six weeks before we first saw her. During this time she had received treatment from her family physician. Her skin had gradually improved, so that when we first saw her she had a mild dermatitis about the face with slight swelling of the eyelids, a dry scaling dermatitis in both antecubital areas, and discrete papulovesicular lesions on the forearms and the dorsum of the hands. She was patch tested to morphine, ethylmorphine hydrochloride, papaverine, apomorphine, codeine and strychnine, all in a dilution of 1 to 100. At the end of twenty-four hours morphine and ethylmorphine hydrochloride gave a moderately positive reaction and papaverine and apomorphine weakly positive reactions. At the end of forty-eight hours the reactions to morphine and ethylmorphine hydrochloride were still moderately positive, while the test to papaverine was slightly less positive and the test to codeine had become mildly positive. The test to apomorphine was now negative, and strychnine at no time showed any results. She was referred back to her family physician and has not been seen since.

COMMENT

The three cases of dermatitis in nurses and the case of dermatitis in a worker with morphine, in addition to the reports of European observers, demonstrate that morphine and other opium derivatives are potential eczematogenous agents. The opium alkaloids, like many other alkaloids and other plant derivatives such as quinine and strychnine, are capable of producing the allergic contact type of dermatitis and should be borne in mind when one sees an eczematous type of dermatitis in nurses, workers in drug houses or others whose occupation or profession requires them to be in contact with these substances. We believe a suspicion of morphine and related compounds as a cause of occupational dermatitis in this group of workers will result in the discovery of many more cases in this country. The eruption in our three nurses appeared first on the hands, with a clinical appearance easily confused with that of ringworm infection. In the case of the morphine tablet molder, if the history was correct, the eruption first appeared in the antecubital areas, probably because the morphine was in powdered form. Other exposed areas were involved subsequently. In all three nurses the dermatitis first appeared on the hands and in cases 1 and 3 later involved other exposed cutaneous areas. Morphine dermatitis, therefore, may remain localized to the hands and thus simulate ringworm infection or contact dermatitis due to other causes such as solution of formaldehyde and soaps. It may primarily involve other areas than the hands and simulate a dermatitis due to plants, dyes or dusts. Extreme degrees of sensitization may be encountered, as in case 1, in which dilutions of 1:1,000,000 produced a strongly positive patch test and exposure to the air in the wards produced clinical symptoms. Our attempts at desensitization in morphine dermatitis have proved a complete failure, as have our attempts at desensitization in other cases of the contact type of dermatitis.

SUMMARY

1. Opium and its compounds, particularly phenanthrene derivatives, deserve more attention as eczematogenous agents and as a cause of the contact type of dermatitis.

2. This group of drugs should be suspected as a cause of eczematous dermatitis of unknown etiology in nurses, physicians and pharmaceutical workers.

417 Delaware Avenue.

ABSTRACT OF DISCUSSION

DR. M. B. SULZBERGER, New York: The striking fact in this report is that it concerns not an isolated instance but three cases of contact-type eczematous dermatitis caused by opium derivatives. That brings up the point as to the practical significance of these substances as causes of contact-type dermatitis; that is, how many cases per thousand are produced by exposure to opium derivatives. The number may be more than was previously believed but still not very great. However, we must always at least think of this possibility, particularly when we face contact-type eczematous dermatitis in physicians, nurses, druggists, persons dealing with pharmaceuticals and their manufacture, and individuals receiving treatment with codeine, morphine or other opium alkaloids. As the authors point out, a few such cases have been reported in the foreign literature. The question brought up by Drs. Jordon and Osborne's paper is also the route of the access to the skin. We know that allergens which produce contact-type eczematous dermatitis may arrive at the skin and produce eczematous reactions not only on exposure from without but also when they are given by injection, by ingestion or in any other way, provided the skin is sufficiently sensitive and that enough of the agent gets to the actual shock tissue. In Jordon and Osborne's series there is one case mentioned in which codeine given by mouth produced the eczematous eruption on the skin but no internal or mucous membrane reactions. Now there are similar analogous situations in contact-type dermatitis to a great variety of allergens. There are cases of eczematous eruptions due to solution of formaldehyde after the ingestion of methenamine and in which no mucous membrane reactions occur; there are cases in which anal suppositories containing contact-type excitants such as resorcinol or ethylaminobenzoate or tars produced generalized eruptions of the skin but no irritation of the anal or rectal mucosa; there are cases in which eye drops containing procaine or atropine, and so on, produced no conjunctivitis but severe dermatitis of the skin of the eyelids and of the face; there are cases in which the allergenic excitants in vaginal tampons and in vaginal suppositories produced no reaction of the mucosa but contact-type dermatitis of the skin. I think we are forced to the conclusion that, while in isolated instances there may be a mucous membrane sensitivity associated with the eczematous sensitivity of the skin, in many other cases the mucous membranes are not sensitive to contact-type allergens. I should like to ask Dr. Jordon and Dr. Osborne whether they found that the phenanthrene derivatives of opium were more likely to cause reactions than the oxyquinoline derivatives.

DR. JAMES W. JORDON, Buffalo: I believe the sensitizing index of morphine is very difficult to determine because morphine is handled by relatively few individuals. The drug is handled chiefly by nurses, pharmacists and, to a lesser extent, by physicians. When we see an eczematous eruption on the hands in nurses, we think of a few things, among them solution of formaldehyde, rubber gloves, soaps and mercury bichloride, and, since the discovery of our first case, morphine. The suspicion of morphine as a cause of eczematous dermatitis in nurses led to the discovery of two additional cases. As far as patch tests are concerned, we had positive tests not only to phenanthrene derivatives but also to benzyloquinoline compounds. In the latter case the tests were not so strongly positive and there is some doubt in my mind whether there is not some contamination with a small amount of morphine. In our cases, at least, we believe that morphine was a responsible agent rather than the other opium derivatives.

EXCISION OF SCAPULA

REPORT OF CASE WITH EXCELLENT
FUNCTIONAL RESULT

EDWIN W. RYERSON, M.D.

CHICAGO

Complete excision of the scapula is performed so rarely that few reports of this procedure can be found in the medical literature. The only reference in recent years is an article by Wakeley,¹ of London. His patient was a young man whose right scapula was removed because of an osteogenic sarcoma. After the excision the trapezius muscle was sutured to the deltoid, and the functional result was very satisfactory.

Nearly all of the reported operations were done for sarcoma or for metastatic carcinoma, with a few scattered cases of necrosis due to injury or infection.

REPORT OF CASE

The following case is of interest for several reasons:

A man of 56 from a neighboring state entered St. Luke's Hospital, Chicago, June 8, 1938, complaining of pain and swelling in the right shoulder. Six years previously he had undergone the resection of several inches of his transverse colon for chronic obstruction, which was said to have been due to carcinoma of the hepatic flexure. He made a rapid recovery from this operation and enjoyed perfect health for the next four years, but in 1936 he began to notice some vague distress in the abdomen, and his appetite was not very good. He continued to work, however, until August 1937, when his right upper arm became painful, and the pain gradually grew worse. His local physician treated him for neuritis with intravenous injections, but the pain persisted, and in May 1938, a month before the trip to Chicago, the shoulder became swollen in the region of the scapula. This swelling was not particularly tender to pressure, but the outer side of the arm was so painful that the patient had to take sedatives three times a day. He was thin and pale, with blood pressure of 108 systolic and

Fig. 1.—Dense osteoplastic tumor of scapula.

78 diastolic. There was no enlargement of any of the lymphatic glands in the neck, axilla or inguinal regions. A long scar occupied the upper portion of the abdomen. The liver dulness extended below the navel about a finger's breadth, but the lower edge and surface were smooth and not sensitive to pressure. The spleen and kidneys were not palpable.

The right scapula was much enlarged, with a domelike appearance, but the skin was smooth and not adherent, with

none of the venous engorgement so often seen in sarcomas. Movement at the shoulder joint was much restricted in all directions and caused pain which radiated down the arm as far as the elbow. The tumor occupied all of the region below the spine of the scapula and seemed to extend upward above this level to the upper angle. It was firm and nonfluctuant and was not particularly tender to pressure. The scapula was not adherent to the chest wall, but its excursions were distinctly limited.

X-ray examination by Dr. Hollis E. Potter showed a dense enlargement of the body of the scapula, with a possible involve-

Fig. 2.—Radiating striations suggestive of osteogenic sarcoma.

ment of the coracoid process. The lateral view showed the radiating striations commonly seen in osteogenic sarcomas. Fluoroscopic examination of the chest by Dr. Potter did not reveal any evidence of metastatic lesions in the lungs, but several calcified lymphatic glands were visible in the thorax.

In considering the diagnosis, the history of a malignant obstruction in the hepatic flexure was highly suggestive, but the patient had been in perfect health for four years after the colonic resection and had had only vague symptoms in the abdomen after that time. The x-ray appearances suggested a new growth of solid consistency and uniform texture, with none of the spotty areas commonly seen in carcinomatous metastases in the flat bones. The lesion was evidently malignant, and the patient was beyond the age when sarcoma is generally encountered, but the x-ray appearance certainly resembled an osteogenic sarcoma.

I considered the advisability of an interscapular-thoracic amputation, but the patient was unwilling to have this. He consented to the excision of the scapula, however, and on June 9 he was anesthetized with nitrous oxide and oxygen. An incision was made from the acromion and carried medially along the spine of the scapula to its inner border and then downward to the lower angle. The flap was retracted and the acromioclavicular joint was separated. The trapezius muscle was then divided and the deltoid pushed upward. The medial and lower borders of the scapula were freed by sharp dissection, the insertion of the serratus magnus muscle. The tendons of the supraspinatus and infraspinatus, the teres minor, the subscapularis and the long head of the biceps were next divided, but it was difficult to separate the coracoid process from its attachments. The capsule was cut with curved scissors, and after the remaining muscles had been divided the scapula could be lifted up without further difficulty.

There was considerable bleeding during the operation, especially from the suprascapular artery. Two chromic catgut sutures were passed through the greater tuberosity and three

Read before the Section on Orthopedic Surgery at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

the clavicle, holding the humerus up in fairly good position. The deltoid was loosely sewed to the trapezius, and the skin was sutured with silkworm gut. No drains were inserted.

A blood transfusion was given, as the patient was beginning to show considerable shock. A Velpeau bandage was applied.

The wound healed by first intention. Ten days after the operation about 3 ounces (90 cc.) of blood was aspirated from the lower angle of the incision. There was little discomfort after the first two days, and the former severe pain disappeared entirely.

The laboratory reported that the tumor was a metastatic glandular carcinoma. Radiating from the original site of the scapular bone were many linear spicules of bone between which were soft gray regions. Histologically there was a basic structure of necrotic bone trabeculae that enclosed marrow spaces filled with granulation and fibrous tissues. The fibrous tissue was extensively invaded by epithelium. The glandular structure resembled that seen in a carcinoma of the colon.

Within three weeks after operation the patient was able to move his arm freely through a range of about 20 degrees

ture on bone metastases from carcinoma in various organs, it is evident that metastasis to the scapula is relatively uncommon. Ghormley and Valls² report one such case in forty-three cases of gastrointestinal carcinoma with bone metastases and state that the incidence

Fig. 3.—Tumor and scapula divided sagittally and spread open.

in all directions. He used the arm in feeding himself and in writing, and he considered that he was greatly benefited by the operation. The former severe pain had entirely disappeared, and he was able to sleep well without any of the sedatives which he had for months been compelled to take. The humerus remained in close apposition to the clavicle, and the deformity was not particularly noticeable. He returned to his home a few days later, and no further pictures were taken, although he came back to the hospital several times for roentgen therapy over the abdomen. He used his arm surprisingly well. The abdominal mass gradually increased in size, and digestive disturbances began to appear. In a few months the opposite shoulder became painful, but no metastasis to the scapula could be discovered. From this time his condition became worse, and by March 1939 he was practically bedridden.

His attending physician reported that on April 8 death occurred from generalized carcinomatosis and that postmortem examination had not been permitted by his family.

Here, then, is a metastatic carcinoma of the scapula, developing five and a half years after the resection of a portion of the colon, with an interval of perfect health lasting four years and with a picture resembling an osteogenic sarcoma. From a survey of the recent litera-

Fig. 4.—One month after excision of entire scapula. Note good approximation and range of active abduction.

of all bone metastases in such cases is from 0.2 to 0.5 per cent, with the highest rate for cancer of the rectum.

Geschickter and Maseritz³ report 356 bone metastases in 5,739 cases of carcinoma of various organs. In five of these 356 cases the scapula was involved.

Probably if I had been certain that the scapular condition was due to metastatic carcinoma the operation

Fig. 5.—One month after operation.

might not have been performed, but the relief from the unbearable pain was so great that it seems to have been justified. The injection of alcohol around the scapula might have given some relief and would perhaps be worth trying in a similar case.

ABSTRACT OF DISCUSSION

DR. W. B. CARRELL, Dallas, Texas: I observed a patient 40 years old with a tumor of the scapula from childhood, evidently an osteochondroma. During the past four or five years there had been definite increase in growth, although no special discomfort with the arm. He came in principally because of the massive tumor on the shoulder and the inconvenience it caused. The case was one of a definite osteochondroma with sharp detail, and nowhere could I find any evidence of a malignant condition. Believing that this was benign, I attempted to preserve as much function as possible and to save the acromion and a part of the coracoid with the glenoid. I believed that I could save the acromion and perhaps gain stability for the shoulder joint later. At the operation it was found when I had gotten in under the tumor that there was a fairly good section of the glenoid and coracoid process, which I was able to leave. As a result I obtained not only good function but excellent stability of the shoulder. The trapezius and the deltoid muscles were left attached. This patient has excellent function, good general position and practically all the motions of the shoulder joint. It is important in excision of the shoulder to preserve the mechanism of attachment of the trapezius and of the deltoid from below so that one gets not only satisfactory position but also stability.

DR. J. ALBERT KEY, St. Louis: I believe that had this patient of Dr. Ryerson's lived and had an opportunity to develop a pseudarthrosis around the head of the humerus he would have had considerable abduction and considerable strength in that

Fig. 6.—Active abduction one month after operation.

shoulder. I have seen one patient with a total excision of the clavicle. She had very little deformity, the shoulder did not drop as would be expected, she had good abduction, and she returned within about two months to regular duty as a trained nurse and has been doing it ever since. Sometimes it is amazing what good results can be obtained after removal of what one customarily thinks of as an extremely important bone. With no clavicle at all, this woman can get her arm up and do her hair.

DR. EDWIN W. RYERSON, Chicago: There are several people in Chicago who were born without any clavicles and they can do a fair day's work. Of course, their shoulders are narrow and the heads of the humeri are in a forward position. A few weeks ago an elderly woman came into my office who twenty-three years ago had a real sarcoma of the clavicle in the middle portion of it, and I excised all except the two ends of the clavicle and put in a bone graft from her tibia. I lost track of her and had not seen her for at least twenty years until she came into my office the other day. She is working in a neighboring town as a beauty specialist, and she says that she can do all the facial work that women require and do it without much difficulty except that her arm gets tired. A fairly good clavicle resulted from the bone graft. I am surprised that Dr. Key did not put a bone graft in that clavicle, although he says he really did not need to.

Clinical Notes, Suggestions and New Instruments

INTERMITTENT OBSTRUCTION OF THE SUBCLAVIAN VEIN

CHARLES W. McLAUGHLIN JR., M.D., AND A. M. POPMA, M.D., OMAHA

Intermittent obstruction of the subclavian vein is very uncommon. Venous obstruction is rarely a factor in cases of cervical rib with arterial compression and associated paresthesias. Swelling of the arm following radical mastectomy is frequently seen as a result of venous or lymphatic obstruction, but it is usually constant, permanent and due to scar tissue or recurrent malignant growth. Matas¹ recently reviewed the subject of primary thrombosis of the axillary vein following strain. Marked swelling of the involved extremity is usual in this condition, but with its development a firm tender thrombosed axillary vein is always associated.

The following report represents an instance of intermittent obstruction of the right subclavian vein developing in a healthy young man and persisting for two years. The absence of any history of trauma or venous thrombosis at the onset of the illness, together with the operative observations and the clinical result following section of the scalenus anticus muscle, warrant presentation of the case in some detail.

REPORT OF CASE

C. M., a farmer aged 24, married, entered the University Hospital, Omaha, for the first time on Feb. 2, 1938. He complained of intermittent swelling and cyanosis of the entire right upper extremity following exertion for the past two years.

The family history was essentially negative except that the patient's father died at the age of 58 with diabetes mellitus. There was no history of tuberculosis, syphilis or heart disease in the family. The patient had been married four years. There were two children living and well. The wife had had no miscarriages.

Prior to the onset of the present illness the patient had enjoyed excellent health and carried out all his duties as a farmer. Eight years previously both bones of the right forearm had been fractured and reduced without x-ray studies. Healing was normal, and there was no residual deformity or weakness. There were no other injuries or operations except a minor procedure which will be mentioned.

Two years before admission while doing heavy work the patient for the first time noted that his right hand, forearm and arm became swollen and blue. This condition appeared suddenly and without any inciting cause and subsided after a few moments of rest. In the succeeding months these attacks of swelling with cyanosis recurred on the average of twice a day, although when the arm was unusually active the swelling persisted most of the day. It would always disappear at night or on rest of the extremity.

A typical attack could be precipitated in about five minutes if the patient chopped wood, drove nails or did similar work. He would then note that the hand, forearm and arm became rapidly swollen, with the skin tense and the entire extremity increased in size. Pain of a severe aching type would develop in the entire arm and demand immediate rest. The entire extremity became blue and definitely cooler than its fellow, and the superficial veins of the hand, forearm, arm and pectoral region would become distended and prominent. This distention of the veins was seen to extend up into the right cervical region on occasions. If the arm was permitted to rest at the side it would lose its blue color and assume a normal size in from ten to fifteen minutes.

One year before entry the patient consulted a physician, who incised the arm over the anterior surface of the biceps muscle. It was reported that a ganglion was removed at this time, although no improvement in the general condition followed the

operation. In recent months the entire extremity and shoulder region had become sore and painful after being swollen intermittently during the day, interfering with the patient's rest. The local application of heat did not benefit these symptoms.

There had been no loss of strength or sensory changes and no associated numbness or tingling while the arm was swollen. The major complaints were a full tight feeling during the period of swelling, associated with intense pain of a muscle fatigue type, and a throbbing sensation followed by intense aching which would persist for some hours.

There was nothing else of import in the systemic history that had any bearing on the present illness.

The patient was powerfully built and well nourished, appeared to be in excellent health and had no complaints other than those already noted.

The skull showed no abnormality and the pupils were round and equal, responding to light and to accommodation. The sclera was normal. The ears and nose were normal. The teeth were in good repair, the tongue was clean and the tonsils were small and atrophic. The thyroid was not palpable. A few small submaxillary and submental glands were palpable. Careful palpation of both cervical regions gave no suggestion of a cervical rib.

The heart was not enlarged, the sounds were of good quality and regular and the pulse rate was 72 per minute; there were no murmurs. The blood pressure was 120 systolic and 76 diastolic in the right arm and 110/70 in the left when the

showed that the pulsations on the two sides were present and grossly equal. After five minutes of active exercise, including flexion and extension of the forearm, and abduction and adduction of the arm, the right upper extremity became definitely enlarged, appearing to be approximately one third larger than the left (fig. 1). The superficial veins on the dorsum of the

hand, the forearm, arm and the right pectoral region became distended and prominent, and the veins in the right cervical region were noticeably enlarged. The entire extremity became dusky blue and cold to touch. During this time the patient complained of intense muscle fatigue incident to the exercise, and a definite diminution in the muscle power of the extremity was seen to develop. After ten minutes' rest the arm had returned to approximately normal size, the veins again became collapsed and the color returned to normal. The muscle power and grip at this time were essentially normal on both sides.

TABLE 1.—Blood Pressure Determinations

Fourth.....	126	60	115	62
Fifth.....	124	64	112	60

The clinical impression was that this patient presented an example of a vascular obstruction on the venous side in the right cervical region, probably at the point where the subclavian vein crossed the first rib. Special investigative procedures were then outlined and carried out in an effort to confirm this impression more definitely.

Blood study showed 88 per cent hemoglobin, 4,850,000 red cells and 7,600 white cells, with 57 per cent polymorphonuclears, 31 per cent lymphocytes, 9 per cent staff cells and 3 per cent monocytes. The urine was amber, with specific gravity of 1.020, and acid reaction. It contained no sugar, no albumin and an occasional white blood cell. Serum Kahn and Kline tests were negative.

The right upper arm measured 12½ inches before exercise and 13½ inches after exercise. The right lower arm measured 11½ inches before exercise and 12½ inches after exercise. Repeated blood pressure determinations were then made on both arms at one minute intervals with two sphygmomanometers and the pressure in the two arms was recorded simultaneously (table 1).

It was observed that the pressure on the right side remained consistently at a higher level than on the left.

Skin temperature studies were carried out at rest under basal conditions after vasodilatation had been induced by immersing the lower extremities in water at 43 C. (109.4 F.) for twenty

Fig. 1.—Appearance of patient five minutes after moderate enlargement of the right arm. The gross enlargement of the arm is readily seen.

extremities were hanging at the side. The chest was clear to percussion and auscultation. The abdomen was normal. The reflexes in all the extremities were normal.

Examination of the two upper extremities disclosed that the right arm was somewhat better developed and more muscular than the left, and the superficial veins on the right side were slightly more prominent while in the position of rest. The entire right upper extremity appeared to be slightly larger than the left. The skin was smooth and elastic, and there was no pitting edema. Palpation of the radial, brachial and axillary arteries

minutes. Readings were also made after active exercise sufficient to produce swelling of the right arm.

This investigation demonstrated a satisfactory skin temperature response in both upper extremities following the release of all vasoconstricting influence. However, readings taken at the same points after exercise demonstrated a marked drop in the skin temperature readings of the right hand, which was in keeping with the clinical observations.

Histamine studies done by the intracutaneous method showed a satisfactory wheal and flare at all levels on both sides.

A study of the venous pressures in the veins of the upper extremities was carried out by Dr. A. L. Bennett of the department of physiology and Dr. Ross MacIntyre of the department of pharmacology. An attempt was made to record venous pres-

sure in the median basilic vein of each arm during the time of forceful rapid gripping of the hand. The patient, however, was unable to produce the typical swelling of the right arm by such limited movements of the hand muscles with the needles in place, and the results obtained from these studies were inconclusive.

X-ray studies revealed that the chest and cervical spine were essentially normal and the mediastinum was clear. The lower end of the right radius showed some cortical thickening at the site of the old fracture, about 4 cm. proximal to the wrist joint.

An anteroposterior study of the right shoulder showed no evidence of pathologic change in bone or soft tissue. There was no evidence of cervical rib.

A film of the right shoulder exposed after the injection of 4 cc. of colloidal thorium dioxide into the median cubital veins showed the cephalic vein to be well visualized to the point of its entrance through the costocoracoid membrane into the axil-

upward to the first rib (figs. 2 and 3). This indicated that the obstruction was intermittent and not the result of thrombophlebitis. There appeared to be a zone of narrowing where the vessel crossed the first rib. The cephalic vein was not visualized at this time. In summary, the right axillary vein, 6 to 18 mm. in diameter, was well visualized to the level of the first rib, with relative narrowing where it crossed the first rib.

Fig. 4.—Condition ten days after operation. The arm was exercised vigorously for fifteen minutes prior to the taking of the photograph. The right arm remained slightly larger than the left, but there was no swelling and no pain.

On the clinical assumption of partial or intermittent obstruction of the axillary vein at the point where it crossed the first rib, surgical intervention was decided on and carried out on March 2.

Cyclopropane anesthesia was administered. The procedure was exploration of the right subclavian triangle and scalenotomy on the right.

An incision 8 cm. in length was made above and parallel to the right clavicle. The platysma was severed and on blunt dissection a large vein measuring at least 1 cm. in diameter became apparent in the base of the wound. From its rather superficial position it was felt that this could not be the subclavian. On further dissection it was seen that the external jugular vein emptied into it and that farther down it joined with the internal jugular vein, which identified it definitely as the subclavian vein. Just distal to the point where it crossed the first rib the vein was seen to be definitely dilated, being at least 2 cm. in diameter. As it crossed the rib it became much narrower, but no definite mechanical obstruction was demonstrable at this point. The vein seemed rather to be somewhat stretched over the first rib at its point of crossing. There was no thickening in the venous wall in this area to suggest the existence of an old thrombosis, nor was there any evidence of old blood pigment about the vein. The subclavian artery was in its normal position and showed no gross lesion. On the assumption that the first rib in its rather high position might possibly be producing a partial mechanical obstruction or venous spasm of the subclavian vein, it was decided to permit the rib to assume a lower position by section of the scalenus anticus muscle. This was done after carefully freeing and separating the phrenic nerve. After section of the muscle the rib was seen to slip downward, allowing the subclavian artery to assume a more anterior position on the first rib and permitting the vein to cross the superior surface of the rib without any evidence

Fig. 3.—A second exposure, made sixty seconds after the completion of the injection of colloidal thorium dioxide, shows the vein less well filled with the opaque medium although the same degree of dilatation exists. Roentgenograms made postoperatively three seconds after injection of 10 cc. of diodrast showed none of the contrast medium to be present in the vein.

lary vein. Further study made after injection of the basilic vein showed it to be visualized to slightly above the point where it pierces the deep fascia, about 1 inch below the axillary fold. These observations suggested partial occlusion of the axillary vein, possibly due to thrombophlebitis.

Further studies of the axillary vein showed it to be well visualized from the level where previous visualization stopped

ESOPHAGOSPASM—BROWNE AND McHARDY

1963

tension. The dilatation in the vein distal to the first rib was much less apparent at the end of the procedure. The neck was closed in layers with one small wick for drainage. The postoperative course was uneventful, and the patient was permitted out of bed on the fifth day after operation. The wound healed by primary union. Ten days after operation the patient was asked again to carry out exercise that formerly produced the swelling of the arm. Repeated attempts were unsuccessful in producing any of the phenomena so typically seen before operation (fig. 4). After operation the arms below the elbow measured $11\frac{1}{2}$ inches before exercise and $11\frac{1}{2}$ inches after exercise. The midarms measured $12\frac{1}{2}$ inches before exercise and $12\frac{1}{2}$ inches after exercise.

A check-up venogram was made in the department of radiology. Further studies of the axillary vein after the intravenous injection of 10 cc. of diodrast showed the vein to be essentially normal in size and position at the completion of the injection. Three seconds after injection of the diodrast, none of the opaque medium remained visualized within the vein. Subjectively the patient said he felt entirely different and had none of the old sensations present in the arm before operation. He was dismissed to return to his work on the farm with instructions to report in three months for follow-up.

On June 20, four months after operation, the patient's right arm was practically normal again. He was experiencing no discomfort and, except for slight weakness on the affected side, he could see no difference in the two arms. On June 1, 1939, sixteen months after scalenotomy was undertaken, the patient was entirely well. The arms were equal in size, full strength had returned, and he was doing heavy work each day with no complaints.

COMMENT

The obstruction demonstrated radiologically by injection of colloidal thorium dioxide was seen to be at the point where the subclavian vein crossed the first rib. This procedure was carried out with the technic of Veal² and was of definite diagnostic value since the positive results of x-ray examination entirely supported the clinical observations.

In considering the possible etiologic factors in this case before operation, primary thrombosis of the subclavian vein was seriously considered. Mats¹ pointed out that the condition may occur idiopathically or after minor degrees of strain. It occurs four times as often in males as in females, and the right arm is affected two and a half times as often as the left. It has been suggested that the subclavius muscle is an important factor in the production of this lesion, trauma and overstretching resulting in rupture of the subclavio-axillary valve which lies beneath the muscle, with the subsequent development of thrombosis.

Venospasm has also been recently suggested as an accessory agent, with the thrombosis resultant from persistent irritation of inflamed or injured perivenous plexuses in the venous wall. Veal and McFetridge³ have recently shown by venograms that primary venous thromboses in this region usually develop in the axillary vein below the head of the humerus and against the subscapularis muscle, not over the first rib and beneath the subclavius muscle as previously suggested.

Prior to surgical exploration, cervical rib had been excluded from consideration and the clinical diagnosis was subclavian vein obstruction, mechanical, due to spasm or resultant from an old venous thrombosis. At operation there was no thickening of the vein wall where it crossed the first rib and the appearance was not that of an old resolving thrombosis. The absence of scar tissue or blood pigment in the root of the neck which might be responsible for the obstruction. The improvement following section of the scalenus anticus muscle was so prompt and dramatic that there can be little doubt that this structure was an important factor in the production of the clinical picture. Normal emptying of the vein visualized by injection following operation confirmed this impression.

² Veal, J. R.: Direct Visualization of the Axillary and Subclavian Veins, *Radiology* 31: 183 (Aug.) 1938.
³ Veal, J. R., and McFetridge, E. M.: Primary Thrombosis of the Axillary Vein, *Arch. Surg.* 51: 271 (Aug.) 1935.

In view of the operative observations, no positive explanation can be offered for the rather sudden development of the clinical syndrome in this case. The relatively high position of the first rib together with a well developed scalenus anticus muscle suggests that pressure was exerted on the subclavian vein during effort. This resulted in the picture of intermittent venous obstruction which appeared with exercise or muscular activity.

CONCLUSION

In a case of intermittent obstruction of the subclavian vein appearing with exercise, it is suggested that mechanical pressure of the first rib on the vein during activity was responsible for the syndrome, since prompt and permanent cure followed section of the scalenus anticus muscle.

A NEW INSTRUMENT FOR USE IN ESOPHAGOSPASM

DONOVAN C. BROWNE, M.D., AND GORDON McHARDY, M.D.
NEW ORLEANS

Bougienage of one variety or another has been practiced for more than fifty years in relieving dysphagia due to cardiospasm. A discussion of the various diagnostic terms applied to this type of pathologic condition of the esophagus such as achalasia, phrenospasm, hiatal esophagismus, megalo esophagus

Fig. 1.—Actual appearance of mercury pneumatic dilator.

Fig. 2.—Artist's sketch of mercury pneumatic dilator.

or idiopathic esophageal dilatation is not pertinent to this paper. The success of this form of therapy and the increasing frequency of diagnosis render our introduction of a most satisfactory combined dilator and divulsor an important item for publication. In a review of the history of dilators adequate mention must be given semistiff fiber bougies and mechanical divulsors inserted through the esophagoscope. Their use necessarily involves a semioperative procedure and they are more applicable in cases in which scarring or fibrous stricturing exists. Sippy's graduated olives, and those of others, in various sizes and

From the Department of Medicine, Tulane University of Louisiana School of Medicine, and the Gastroenterology Clinic, Toussaint Infirmary, George P. Pilling & Son Company, Philadelphia, makers of this instrument, cooperated with the authors in working out the problems of construction.

shapes attached to a fiber and guided by a swallowed thread, are introduced fearlessly by persistent adherents. They are probably safest in expert hands. We have seen under the fluoroscope an apparently taut cord loosen, the bougie fail to engage the cardia and pass blindly into a dilated esophageal pouch. Because of this as well as of other obvious limitations, they must be reserved for the expert endoscopist.

Retrograde dilation with Tucker's instrument and divulsion manually or by forceps from the gastric side are major surgical procedures reserved for those few instances in which adequate indications exist.

Hurst introduced his mercury filled bougies in 1913. They are rubber tubes varying in diameter (from 21 to 40 English), 31 inches long and each containing the same quantity of mercury (21 ounces). These are carried and guided through the esophagus by their weight, opening a passageway by their size.

These dilators, in our experience, are the easiest passed; they cause less discomfort and are unquestionably the safest instruments available in properly indicated cases. Successively larger tubes are passed at a single sitting, and in most instances the largest one meets with only slightly more resistance than the smallest.

Additional factors in the use of these bougies include the following: 1. In the instance of narrowing at sites, in addition to that at the cardia, all are dilated to the same extent by the one passage. 2. Patients have been taught to use the bougies in selected instances. 3. No fatality has been recorded from the use of this procedure. 4. It is obvious that these bougies have limitations and are best employed when the cardiac opening remains dependent and the existing pathologic condition has not brought about a great sacculatation at a level below the hiatus, although we have employed them quite successfully in severe cases. 5. The large size, No. 40, often proves annoying to patients because of the bulk in the pharynx.

The history of the bag divulsion dates back to J. C. Russel's work of 1898. In 1906 at the Mayo Clinic Plummer modified

Fig. 3.—Dilator introduced into stomach; irregularity in outline as marked by arrow represents the metallic ring at each extreme of the pneumatic bag.

It requires a source of running water and is not portable and for this reason is not as practical as could be wished. Failure to place the dilator, unsatisfactory results due to improper technique, considerable pain and a mortality percentage are admitted; however, it has a definite advantage in that divulsion is achieved by its use.

In 1929 Frank Smithies designed the pneumatic dilator modification of Plummer's apparatus in an effort to remedy proved limitation of the latter divulsor. Smithies' dilator, being portable, requiring no special water supply, being devoid of whalebone staff but having a metal shaft with safety control, and being of inexpensive construction, was a notable achievement.

It rendered fluoroscopic control of divulsion dilation practical. Its only essential distinction from the Plummer dilator, however, is that it is pneumatic.

Ten years has passed since Smithies' pneumatic bougie was introduced and there has been no further notable advance in instruments. There have been minor modifications of the pneumatic bougie and advocates of a barium bag, but none of these have been of great value. Prior to perfecting the combine

Fig. 4.—Dilator in place and distended with air. Arrow is at margin of pneumatic bag, which is faintly outlined.

apparatus which we now introduce we use equipment similar to Smithies', eliminating the objectionable steel shaft, thus increasing the safety factor but still having to resort to a swallowed thread for reassurance and guidance in most instances. In September 1938 work was started on the instrument which we now present, and the final plans and specifications were forwarded to George P. Pilling & Son Company in January 1939.

This new dilator and divulsor combines the principles of Hurst, Plummer and Smithies and achieves a position of maximal efficiency and safety.

It is a number 21 Hurst mercury tube; on the distal end, 7.5 cm. from the tip, has been incorporated a rubber covered silk bag 11 cm. in length to which a small catheter runs through the mercury filled tube. By this means distention, under the control of a sphygmomanometer, may be effected.

The distinct advantages of this instrument are that: 1. A swallowed guiding thread is not required; it is easily passed, being the size of the small Hurst dilator. It is carried through by virtue of its contained 21 ounces of mercury, which is sufficient to force the closed sphincter and which is in itself a guide but which is not sufficiently forceful to traumatize or perforate the esophagus. 2. This type dilator is most easily passed with less discomfort than any other type and does not show any tendency to coil in a dilated prediaphragmatic dilatation, as might be suggested by some. 3. Only a single instrumentation is required, as contrasted to the passing of an olive prior to the use of a Plummer dilator and the use of graduated Hurst bougies. 4. It offers controlled pneumatic divulsion, which is more practical and safer than hydrostatic dilation, and this in combination with the bougie qualifications of the Hurst dilator. 5. It is applicable to x-ray examination as is illustrated here.

This dilator is not presented with the idea that it is applicable in all instances, any more than other instruments may meet all emergencies, but rather that it fills a need most frequently encountered.

1520 Aline Street.

Number of Persons Infected by One Mosquito.—It is important to know whether an *Anopheles* once infected (with malaria) can infect more than one person without again feeding on infective blood. . . . In a most instructive series of experiments conducted by Mayne he reports that one mosquito proved to be the sole infecting agent in three cases. *Mitzman* used *Anopheles punctipennis* (Say) with *Plasmodium vivax*. He also demonstrated in eleven experiments that short exposure to bites was sufficient to cause successful transmission of the disease.—Hermes, William B.: *Medical Entomology*, New York: Macmillan Company, 1939.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

HEINZ STRAINED PEARS AND PINEAPPLE

Manufacturer.—H. J. Heinz Company, Pittsburgh.

Description.—Canned strained mixture of pears and pineapple.

Manufacture.—Fresh pears are sorted, peeled by mechanical peelers, by scalding, or by hand peeling. The peeled pears are cored, trimmed, washed and precooked with direct steam under light pressure. Definite proportions of canned or fresh crushed pineapple are added and the mixture is strained in an atmosphere of steam, filled into enamel-lined cans, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 84.9%, total solids 15.1%, ash 0.4%, salt 0.05%, protein ($N \times 6.25$) 0.4%, fat (ether extract) 0.04%, crude fiber 1.0%, total carbohydrate other than crude fiber (by difference) 12.9%, sucrose (Munson and Walker Method) 10.1%, starch (by difference) 2.8%, acidity as citric 0.37%.

Calories.—0.54 per gram; 15.3 per ounce.

Vitamins.—Protocols of biologic assay submitted by the manufacturer indicate that Heinz Strained Pears and Pineapple has the following approximate vitamin content:

Vitamin A, 1.7 U. S. P. units per gram; 50 per ounce.

Vitamin B₁ (thiamin), 0.24 international unit per gram; 7 per ounce (equivalent to 0.21 mg. of thiamin per ounce).

Vitamin G (riboflavin), 0.17 Sherman-Bourquin unit per gram; 5 per ounce.

It is further reported that the product contains 0.03 mg. of ascorbic acid per gram, 0.85 per ounce (equivalent to 0.6 international unit of vitamin C per gram, 17 per ounce) as determined by chemical titration.

TURKEY BRAND GOLDEN SYRUP

Manufacturer.—J. Stromeyer Company, Philadelphia.

Description.—Corn syrup flavored with refiners' syrup.

Manufacture.—Formula proportions of the two ingredients are blended and packed in tins.

Analysis (submitted by manufacturer).—Moisture 22.6%, total solids 77.4%, ash 1.2%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 0.2%, reducing sugars as invert sugar 32.4%, sucrose 9.7%, dextrin 28.3%, crude fiber none, carbohydrates (by difference) 75.9%, Baume 41°.

Calories.—3.05 per gram; 87 per ounce.

PRUDENCE BRAND ROAST BEEF HASH

Manufacturer.—Boston Food Products Company, Boston.

Description.—Canned roast beef hash prepared from cooked potatoes, roasted beef, roasted beef juices; seasoned with salt and pepper.

Manufacture.—Selected beef (boneless chucks, shoulders and rounds) U. S. Inspected and Passed by the Department of Agriculture, is cut in small pieces, sinew, bristle and excess fat are removed, and it is roasted until well done without the addition of water. Potatoes are mechanically peeled, trimmed, washed and cooked. Formula proportions of the ingredients are mixed, mechanically chopped and filled into cans, which are heated, sealed and heat processed. The product is manufactured under the supervision of the Bureau of Animal Industry.

Analysis (submitted by manufacturer).—Moisture 70.0%, total solids 30.0%, ash 2.4%, fat (ether extract) 6.4%, protein ($N \times 6.25$) 9.5%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 11.4%.

Calories.—1.41 per gram; 40 per ounce.

SAVERY-SAVORY BRAND MUSHROOMS, BUTTONS, SLICES, AND STEMS AND PIECES

Manufacturer.—The Great Western Mushroom Company, Denver.

Description.—Hothouse mushrooms, canned as buttons, slices and stems and pieces, slightly seasoned with salt.

Manufacture.—Mushrooms, grown under sterile conditions from mushroom spawn, are cultured on trays in a thin layer of moist rich top soil covering a mixture of dirt and manure in dark houses maintained at a constant temperature. The mushrooms are picked by hand, conveyed to the cannery, trimmed, and sorted by hand. Stems and buttons are graded mechanically and some mushrooms are sliced mechanically. The mushrooms are immersed in boiling water for five minutes, weighed into cans which are filled with hot water, salt is added, and the cans are sealed and heat processed.

Analyses (submitted by manufacturer).—

	Buttons, per cent	Slices, per cent	Stems and Pieces, per cent
Moisture	91.7	93.4	92.2
Total solids	8.3	6.6	7.8
Ash	1.6	1.5	1.6
Sodium chloride (NaCl)	0.9	1.1	1.2
Fat (ether extract)	0.2	0.2	0.2
Protein ($N \times 6.25$)	3.1	2.6	2.7
Crude fiber	0.7	0.7	2.9
Carbohydrate other than crude fiber (by difference)	2.7	1.6	0.4

Calories.—Buttons, 0.25 per gram; 7 per ounce.

Slices, 0.19 per gram; 5 per ounce.

Stems and pieces, 0.14 per gram; 4 per ounce.

(1) BRUCE'S JUICES BRAND ORANGE JUICE, UNSWEETENED

(2) BRUCE'S JUICES BRAND ORANGE JUICE, SUGAR ADDED

Manufacturer.—Bruce's Juices, Inc., Tampa, Fla.

Description.—(1) Canned, unsweetened orange juice.

(2) Canned orange juice with added cane sugar.

Manufacture.—(1) Sound, tree-ripened oranges are washed and mechanically cut in half and the juice is extracted by reamers operated by hand or mechanically. The juice is strained, deaerated, pasteurized and filled into cans. The cans are sealed and cooled.

(2) The juice is prepared and canned as described for Bruce's Juices Brand Orange Juice, Unsweetened. A small amount of sugar is added after the juice is strained.

Analyses (submitted by manufacturer).—(1) Moisture 87.5%, total solids 12.5%, ash 0.4%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 0.4%, sucrose 1.9%, reducing sugar as invert 6.9%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 11.5%, titratable acidity as anhydrous citric acid 1.2%, vitamin C 51.4 mg. per hundred cubic centimeters. (2) Moisture 84.6%, total solids 15.4%, ash 0.3%, fat (ether extract) 0.1%, protein ($N \times 6.25$) 0.4%, sucrose 5.0%, reducing sugar as invert 6.7%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 13.3%, titratable acidity as anhydrous citric acid 1.2%, vitamin C 50.3 mg. per hundred cubic centimeters.

WINDSOR BRAND EVAPORATED MILK

Manufacturer.—Windsor Evaporated Milk Company, Cleveland (an associate of the Telling-Belle Vernon Company, Cleveland, and subsidiary of the National Dairy Products Corporation).

Description.—Canned unsweetened evaporated milk.

Manufacture.—Selected milk is inspected, tested, preheated, evaporated under vacuum, homogenized, cooled, standardized to meet government requirements for butter fat and total solids, filled into cans, sealed and sterilized.

Analysis (submitted by manufacturer).—Moisture 73.7%, total solids 26.3%, ash 1.6%, fat (ether extract) 7.8%, protein ($N \times 6.38$) 6.9%, lactose (by difference) 10.0%.

Calories.—1.38 per gram; 39 per ounce.

SATURDAY, NOVEMBER 25, 1939

The Platform of the American Medical Association

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

8. Expansion of public health and medical services consistent with the American system of democracy.

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

In the various actions of the House of Delegates during the special session held in Chicago in September last year, and again at the meeting in St. Louis, certain constructive proposals were made which had the full approval of the House of Delegates. Now the Board of Trustees of the American Medical Association has formulated these concepts into a constructive platform for the American Medical Association. This platform is set up as a guide to indicate the trend which the American Medical Association believes should be followed in the development of health activities and medical care for the people of the United States.

1. The establishment of an agency of federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

Today the medical and health functions of the United States are divided among a multiplicity of departments, bureaus and federal agencies. Thus, the United States Public Health Service is in the Federal Security Agency; the Children's Bureau in the Department of Labor; the Food and Drug Administration in the Department of Agriculture; the Veterans' Administration and many other medical functions are separate bureaus of the government. The WPA, CCC and PWA are concerned with a similarity of efforts in the field of preventive medicine. The Federal Works Administration and the Federal Housing Administration also have some medical functions.

Since 1875 the American Medical Association has urged the establishment of a single agency in the federal government under which all such functions could be correlated in the interest of efficiency, the avoidance of duplication and a saving of vast sums of money. Such a federal health agency, with a secretary in the cabinet or a commission of five or seven members, including competent physicians, would be able to administer the medical and health affairs of the government with far more efficiency than is now done.

2. The allotment of such funds as the Congress may make available to any state in actual need for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

The physicians of the United States have given freely of their time and of their funds for the care of the sick. Their contributions to free medical service amount to at least \$1,000,000 a day. The physicians of this country have urged that every person needing medical care be provided with such care. They have urged also the allotment of funds for campaigns against maternal mortality, against venereal disease and for the investigation and control of cancer. The medical profession

does not oppose appropriations by Congress of funds for medical purposes. It feels however that, in many instances, states have sought aid and appropriations for such functions without any actual need on the part of the state, in order to secure such federal funds as might be available. It has also been impossible, under present technics, to meet actual needs which might exist in certain states with low per capita incomes, with needs far beyond those of wealthier states, in which vast sums are spent.

It is proposed here simply that Congress make available such funds as can be made available for health purposes; that these funds be administered by the federal health agency, mentioned in the first plank of this platform, and that the funds be allotted on proof of actual need to the federal health agency, when that need is for the prevention of disease, for the promotion of health or for the care of the sick.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

Obviously if federal funds are made available to the individual states for the purposes mentioned in the second plank of this platform, there might well be a lessened tendency in many communities to devote the community's funds for the purpose and, in effect, to demand that the federal government take over the problem of the care of the sick. Hence it is suggested that communities do their utmost to meet such needs with funds locally available before bringing their need to the federal health agency, and that the federal health agency determine whether or not the community has done its utmost to meet such need before allotting federal funds for the purpose.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

The medical profession is not static. It wishes to extend preventive medical service to all the people within the funds available for such a purpose. Obviously, this will require not only a federal health agency which may make suggestions and initiate plans but also a mechanism in each community for the actual expansion of preventive medical service and for the proper expenditure of funds developed both locally and federally. In the development of new legislation, such mechanism may be suitably outlined.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

The medical profession does not yield to any other group in this country in its desire to extend medical

care to all those unable to provide themselves with medical service. The American Medical Association through its House of Delegates has already recognized the possible existence of a small group of persons able to provide themselves with the necessities of life commonly recognized as standard in their own communities but not capable of meeting a medical emergency. It is recognized, however, that only persons of the same community fully familiar with the circumstances can determine the number of people who come properly under such classification and that only persons in actual contact with such instances are capable of administering suitably and efficiently the medical care that may be required. Hence it is the platform of the American Medical Association that medical care be provided for the indigent and the medically indigent in every community but that local funds be first utilized and that local agencies determine the nature of the need and control the expenditure of such funds as may be developed either in the community or by the federal government.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

In the so-called National Health Program it is asserted that one half the counties of the United States are without suitable hospitals, and vast sums are requested for the building of new hospitals. In contrast, reputable agencies within the medical profession assert that there are only thirteen counties more than 30 miles removed from a suitable hospital and that in eight of those thirteen counties there are five persons per square mile. In the United States today the percentage of hospital beds per thousand of population is higher than that of any other comparable population in the world. This fact is completely ignored by those who would indulge in a program for the building of great numbers of new hospitals.

Moreover, it seems to be taken for granted that hospital building has languished in recent years, whereas considerable numbers of hospitals have been built with federal funds by various state agencies and also by the PWA, the WPA and the Federal Works Administration.

Analyses may indicate that in many instances such hospitals were built without adequate study as to the need which existed or as to the possible efficient functioning once it was erected. Moreover, there is evidence that in recent years many of the hospitals of the United States known as nonprofit voluntary hospitals have had a considerable lack of occupancy, owing no doubt to the financial situation in considerable part. It seems logical to suggest then that such federal funds as may be available be utilized in providing the needy sick with hospitalization in these well established existing institutions before any attempt is made to indulge in a vast

building program with new hospitals. In this point of view the American College of Surgeons, the American Hospital Association, the Catholic Hospital Association, the Protestant Hospital Association and practically every other interested voluntary body agree.

Again, it has been argued that the demands for medical care in some sections of the country might require the importation of considerable numbers of physicians or the transportation of numbers of physicians in the areas in which they now are to other areas. In this connection it would seem to be obvious that a change in the economic status of the communities concerned would result promptly in the presence of physicians who might be seeking locations. The utilization of existing qualified facilities would be far more economical than any attempt to develop new facilities.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

In the United States today our sickness and death rates are lower than those of any other great country in the world. This fact was recognized by the President of the United States when he sent the National Health Program to the Congress for careful study. The President emphasized that a low death rate may not mean much to a man who happens to be dying at the time of tuberculosis. The medical profession recognizes the importance of doing everything possible to prevent every unnecessary death. At the same time it has not been established by any available evidence that a change in the system of medical practice which would substitute salaried government doctors for the private practitioner or which would make the private practitioner subject to the control of public officials would in any way lower sickness and death rates.

There exists, of course, the fact that some persons are unable to obtain medical service in the circumstances in which they live and that others, surrounded by good facilities, do not have the funds available to secure such services. Obviously, here again there is the question of economics as the basis of the difficulty and perhaps lack of organization in distribution of medical service and a failure to utilize new methods for the distribution of costs which might improve the situation.

The medical profession has approved prepayment plans to cover the costs of hospitalization and also prepayment plans on a cash indemnity basis for meeting the costs of medical care. It continues, however, to feel that the development of the private practice of medicine which has taken place in this country has led to higher standards of medical practice and of medical service than are elsewhere available and that the maintenance of the quality of the service is fundamental in any health program.

8. Expansion of public health and medical services consistent with the American system of democracy.

Careful study of the history of the development of medical care in various nations of the world leads to the inevitable conclusion that the introduction of methods such as compulsory sickness insurance, state medicine and similar technics results in a trend toward communism or totalitarianism and away from democracy as the established form of government. The intensification of dependence of the individual on the state for the provision of the necessities of life tends to make the individual more and more the creature of the state rather than to make the state the servant of the citizen. Great leaders of American thought have repeatedly emphasized the fact that liberty is too great a price to pay for security. George Washington said "He who seeks security through surrender of liberty loses both." Benjamin Franklin said "They that can give up essential liberty to obtain a little temporary safety deserve neither liberty nor safety."

In these times, when the maintenance of the American democracy seems to be the most important objective for all the people of this country, the people may well consider whether some of the plans and programs that have been offered for changing the nature of medical service are not in effect the first step toward an abandonment of the self reliance, free will and personal responsibility that must be the basis of a democratic system of government.

THE SECRETARIES AND EDITORS CONFERENCE

The Annual Conference of Secretaries of Constituent State Medical Associations and Editors of State Medical Journals, held in Chicago on November 17 and 18, proved to be one of the most inspiring and stimulating sessions thus far held under the auspices of the American Medical Association. Among the highlights of the program arranged by Dr. Olin West were the report on "The Study of Medical Care in the United States," read by C. E. Nyberg, of the Bureau of Medical Economics; the analysis of present legislation for a National Health Program by Dr. W. C. Woodward, of the Bureau of Legal Medicine and Legislation, and the report of the Board of Trustees relative to the platform of the American Medical Association, which appears in this issue of *THE JOURNAL*.

The remaining sessions were devoted largely to consideration of actual reports on plans now subject to experiment in various states, particularly that of New Jersey presented by N. M. Scott, of Michigan by L. Fernald Foster, of Washington by V. W. Spickard, and of Pennsylvania by W. F. Donaldson. Moreover, there were discussions of rural medical service by F. S. Crockett, of the Committee on Legislative Activities.

the American Medical Association, and an analysis of the way in which the state of Indiana meets legislative problems, by Thomas A. Hendricks, executive secretary for that state. These reports proved to be clinical sessions dealing with economic experiments. Exhaustive discussions of experiences not only with these plans but with various federal and other agencies now interested in this field brought to light important information. Extensive abstracts of this material will be published in the Organization Section of forthcoming issues of THE JOURNAL.

Similarly, the dinner for state editors, which was attended by practically all of the secretaries as well, proved to be an editorial clinic in which the demonstrator was Dr. Samuel J. Kopetzky, of New York, who spoke on "The Role of the State Medical Journal in Organized Medicine." The discussion on this topic concerned not only the actual preparation of editorials but also the relationship of the state journal to public relations for state medical societies and even such minute problems as the proper use of the editorial "we."

These meetings serve particularly to coordinate the work of the headquarters office of the American Medical Association with the constituent state medical associations, whose secretaries and editors are the chief functioning units in the work of the American Medical Association.

WHY ACETARSONE FOR SYPHILIS?

The use of acetarsones as an antisyphilitic drug which could be taken by mouth has been reviewed recently by Pillsbury and Perlman,¹ who studied 187 cases of congenital syphilis at the Sigma Clinic of the Children's Hospital, University of Pennsylvania School of Medicine. Their conclusions corroborate the previous statements made by the Council on Pharmacy and Chemistry² concerning the use of acetarsones in the treatment of syphilis. The investigators emphasize that acetarsones, although an active antisyphilitic agent by mouth, is less rapid in action than arsphenamine and is inferior to both arsphenamine and bismuth preparations in arresting congenital syphilis. In their series of cases they found a high incidence of reactions. They concluded, indeed, that adequate experimental background for determination of the toxicity and spirocheticidal effect of individual lots of acetarsones is not available. In addition they observed that regularity of attendance of patients at the clinic was not increased by the use of oral therapy as compared to the injection method of administration and that acetarsones is probably not administered as directed to patients treated at home. They stressed that the evaluation of the responsibility

of the patient or guardian is one of the most important features of oral therapy and that lack of cooperation is a contraindication to the use of acetarsones. The authors indicated that for newborn infants the use of a system of dosage based on weight is essential and stated that the system of Bratusch-Marrain³ seems the best available.

Pillsbury and Perlman believe that the convenience and time-saving advantages of oral therapy are not sufficient to substitute for the administration of more effective, less dangerous compounds which must be given parenterally, granted that this may sometimes prove difficult. It might be argued that the high percentage of Negroes among their patients might account for the lack of cooperation or irregularity of attendance. The fact remains that in the case of children the responsibility of adequate and subtoxic dosage is dependent largely on the parent of the patient treated orally at home. This responsibility might also be obviated by insisting that the patient receive the prescribed oral medication from the physician in his office, in which case the advantage of time saving would be lost, plus the inconvenience of frequent visits.

The ease of administration of an oral spirocheticide is sufficiently desirable to encourage the search for an effective antisyphilitic drug which can be given by mouth. Every preparation must be considered, however, in relation to others as to its effect on syphilis, irrespective of the mode of administration required. Because of its inferiority of effectiveness, acetarsones cannot be recommended for general use in the treatment of syphilis. Although there have been numerous favorable reports⁴ of the value of acetarsones for syphilis, there are also others⁵ which criticize its use severely. Whipple and Dunham⁶ state that the period of observation for any adequate evaluation of acetarsones has been sufficient in only four studies. In most reports the ease of administration has been emphasized as an important advantage of acetarsones therapy. This should not excuse the critical examination of the results obtained, which thus far seem to be poorer with acetarsones than with other arsenicals of lesser toxicity.

In addition to the inferiority of results obtained in congenital syphilis with acetarsones, it has been found to be undesirable from the point of view of toxicity. The evidence concerning this is conflicting but has been adequately summarized by Rosahn and Kemp.⁷ They were unable to establish any definite dosage range as safe for rabbits and found that the drug in therapeutic

doses was sometimes lethal. There was also variation in the toxicity of various lots of the commercial drug. The small difference between the toxic and the therapeutic dose constitutes an additional objection to acetarsone.

Current Comment

THE COLLEGE OF SURGEONS AND THE AMERICAN MEDICAL ASSOCIATION

One of the most important conferences to be held for the promotion of efficiency in the administration of medical affairs in this country took place in the headquarters office of the American Medical Association on November 16, when the Board of Regents and some of the headquarters officials of the American College of Surgeons met with the Board of Trustees and the headquarters officials of the American Medical Association.

Board of Regents of American College of Surgeons, Board of Trustees of American Medical Association, and headquarters officials. Back row from left to right: Dr. Olin West, Miss Eleanor K. Grimm, Dr. Malcolm T. McEachern, Dr. James R. Bloss, Dr. Nathan B. Van Etten, Dr. Fred A. Besley, Dr. James Monroe Mason, Dr. Austin A. Hayden, Mr. Will C. Braun, Dr. W. D. Cutter, Dr. Irvin Abell, Mr. Homer F. Sargent, Dr. Gilbert J. Thomas, Dr. George P. Muller, Dr. R. L. Sensenich, Dr. Walter S. McClellan, Dr. Rock Sleyster. Front row: Mr. Thomas R. Gardiner, Miss Jewel Whelan, Dr. Ralph A. Fenton, Dr. E. L. Henderson, Dr. H. H. Shoulders, Dr. Alton Ochsner, Dr. Harry Gradle, Dr. Howard C. Naffziger, Dr. Morris Fishbein, Dr. Arthur M. Shipley, Dr. Arthur W. Booth, Dr. Fred Collier, Dr. Herman L. Kretschmer, Dr. Thomas B. Cullen, Dr. Alphonse McMahon, Dr. Roger I. Lee, Dr. George W. Crile.

ciation. The session was devoted largely to a consideration of increasing efficiency, avoiding duplication, and enhancing the importance of the inspection of hospitals, not only for their utility in caring for the sick but also in relationship to their work in surgery and their availability as institutions for the education of interns and for the establishment of residencies in the specialties. The many years of experience of the Council on Medical Education and Hospitals and of the Hospital Section of the American College of Surgeons, which are now cooperating in these efforts, warrant the placing of full reliance on this joint effort. Consideration was given also to many questions concerned with the appointments of the staffs of hospitals and the manner in which the two organizations could function together in the maintenance of the quality of medical service in our country.

OHIO HEALTH DEPARTMENT REORGANIZED

The health department of the state of Ohio has been reorganized "to enhance its efficiency by removing it, so far as possible, from political interference."¹ *Ohio Public Health*² reports the appointment of a public health council provided by a new law passed by the last session of the Ohio general assembly.² The new council consists of six members, of whom three are physicians, one is a dentist, one is president of the Ohio Congress of Parents and Teachers, and one is a sanitary engineer. The former public health council consisted of five members all appointed by the governor. The new organization provides that the director of health shall be appointed for five years instead of being removable at the pleasure of the governor. He cannot now be removed by the incoming governor except by written request of a majority of the public health council.

cil. The enactment of legislation to remove public health departments from politics is always encouraging. Of course the functioning of the new law will depend on how it is administered, but even in the hands of self-seeking politicians such laws have a tendency to protect the tenure of office of a competent official and thus give continuity and integration to public health work in the state. The presence of physicians and dentists representing the organizations of these professions and of representatives of civic organizations on public health boards or councils tends to discourage political meddling, which has been one of the most discouraging factors with which sincere public health officials have been forced to contend.

Association News

THE SCIENTIFIC EXHIBIT

Application blanks for space in the Scientific Exhibit at the New York Session, June 10-14, 1940, are now available. Requests for blanks and for information concerning the Scientific Exhibit should be sent to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

MEDICINE IN THE NEWS

The seventh season of broadcasting by the American Medical Association over the facilities of the National Broadcasting Company and affiliated stations opened Thursday November 2 at 4:30 p. m. eastern standard time (3:30 central standard time, 2:30 mountain time and 1:30 Pacific time). The title of the program will be Medicine in the News.

True to their title, the programs consist of dramatizations based on what is happening in the world of medicine. Each program will include a principal news item from THE JOURNAL or some other reputable medical source or from Hygeia. This will be followed by one or more highlights on current medical news. Each program will close with a question of the week drawn from the question and answer correspondence of Hygeia. A question will be asked each week and answered the following week.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

A Definition of Epilepsy.—At a meeting October 7 the California State Board of Public Health defined "epilepsy" as follows: Any condition which brings about momentary lapses of consciousness, and which may become chronic, shall be considered reportable under the term "epilepsy." This action was taken in view of recent legislation making epilepsy a reportable disease. Physicians are now required to report cases to the local health officers, who will in turn report to the state department of health.

Society News.—A symposium on physical therapeutic methods was presented before the San Francisco County Medical Society November 14 by Drs. Tilman Howard Plank, Harry Glenn Bell, William C. Deamer, Alice Potter, William H. Northway and Frances Baker. All are of San Francisco. The medical and surgical aspects of hypertension were discussed before the Alameda County Medical Association, Oakland, November 20 by Drs. Archibald A. Alexander, Hugh Gordon MacLean and William Whitfield Crane, Oakland.

Postgraduate Assembly.—The Huntington Memorial Hospital and the Stanley P. Black Memorial Association, Pasadena, sponsored a postgraduate assembly October 2-7. Among the speakers were:

- Dr. Loren R. Chandler, San Francisco, Abdominal Surgery in Children.
- Dr. Roy E. Thomas, Los Angeles, The General Management and Treatment of Pneumonia.
- Dr. Hans Lisser, San Francisco, Childhood and Adult Hypothyroidism and the Proper Use of Thyroid Substance.
- Dr. Frank S. Doley, Los Angeles, Recent Advances in the Surgical Treatment of Diseases of the Chest.
- Chauncey D. Leake, Ph.D., San Francisco, Practical Aspects of Recent Advances in Pharmacology.
- Dr. Ludwig A. Emge, San Francisco, The Toxemias and Other Complications of Pregnancy.

FLORIDA

Society News.—At a meeting of the Dade County Medical Society recently the speakers were Drs. Elmer H. Adkins, Miami Beach, on "Thyroglossal Duct Cysts and Fistulae" and Iva C. Youmans, Miami, "Technical Requirements as Related to the Growth of Medicine."—The Duval County Medical Society was addressed in Jacksonville October 3 by Dr. Lincoln S. Lahtie on "Quinidine in Some Manifestations of Heart

Disease."—At a recent meeting of the Pinellas County Medical Society Dr. Nonie W. Gable, St. Petersburg, spoke on ethmoiditis.

Basic Science Board Appointments.—Members of the state board of examiners in the basic sciences for Florida include the following recently appointed by the governor, according to the *Journal of the Florida Medical Association*: Mark Wirth Emmel, D.V.M., professor of veterinary science, University of Florida, Gainesville, chairman; John Ferguson Conn, Ph.D., secretary, professor of chemistry, John B. Stetson University, Deland; Ezda May Deviney, Ph.D., professor of zoology, Florida State College for Women, Tallahassee; Jay F. W. Pearson, Ph.D., professor of zoology, University of Miami, Coral Gables, and Donald D. Bode, Ph.D., professor of chemistry, Tampa University.

District Health Units Abolished.—Newspapers report the discontinuance of the five district health units in Florida established to render emergency service in counties without full time health units. Hereafter this service will be administered by the state department direct from the central office at Jacksonville. The district units were located in Marianna, Jacksonville, Ocala, Bartow and West Palm Beach. According to the report, abolition of the health districts was recommended by the American Public Health Association in a recent statewide survey of Florida's public health conditions. Concurring in the recommendation, the U. S. Public Health Service has refused to allow further use of federal allocations to Florida for this type of service, it was stated. It was also said that the money used to finance these districts should be devoted to establishing full time health departments.

ILLINOIS

Personal.—Dr. Alfred S. Ash, formerly of Chicago, has been placed in charge of the Soldiers' and Sailors' Home and Hospital, Quincy, succeeding the late Dr. Chauncey E. Ehle. —Dr. Charles E. Soule, Beardstown, was recently guest of honor at a banquet given by the Cass County Medical Society in recognition of his fifty years in the practice of medicine. The Illinois State Medical Society presented him with a certificate and medal.

Report on Trachoma.—A total of 161,903 persons have attended the five trachoma clinics of the state during the five years of their existence. These clinics, established about 25 miles apart in Shawneetown, Jonesboro, Eldorado, Herrin and Vienna, give treatments each week to about 700 persons of all ages and in varying stages of trachoma. On August 12 there were 3,276 cases of positive trachoma under care at the five clinics, with 1,295 suspects under observation. According to *Welfarc*, 191 operations were performed in the past year. Of the 331 new patients with positive trachoma received for treatment at the clinics in the year ended June 30, 1938, there were thirty-three, or 10 per cent, who had beginning trachoma; fifty-five were in the second stage, sixty-six in the third stage and 177 in the fourth stage. Many persons who came to the clinics for diagnosis did not have trachoma but suffered from other eye conditions which threatened their vision. Of these, eighty-eight were sent to the Illinois Eye and Ear Infirmary during the past year and twenty-four more are waiting until beds are available.

Chicago

Hospital News.—The Illinois Eye and Ear Infirmary has instituted a course of training for orthoptic technicians following principles outlined by the recently organized American Orthoptic Council. Four technicians will be taken for a six months course beginning in January.

The Bacon Lectures.—Dr. Robert Meyer, formerly director of Pathological Institute (Gynecological Clinic) and honorary professor at Friedrich-Wilhelms University, Berlin, will deliver the Charles Sumner Bacon Lectures for 1939-1940 at the Medical and Dental College Laboratories Building, University of Illinois College of Medicine December 6-7. His subjects will be "The Basis of the Histological Diagnosis of Carcinoma" and "Diagnosis of Early Carcinoma of the Cervix."

Grants for Research.—The Institute of Medicine of Chicago announces that the entire Elizabeth McCormick Child Research Grant of \$1,000 for 1939-1940 will be used for the encouragement of research and that awards have been made to Dr. Mila I. Picree, Evanston, for work on leukemia; to Dr. Heyworth N. Sanford for a study of the role of the qualitative platelet factors in the coagulation of the blood, and to Dr. Clayton J. Lundy for a study of heart murmurs in children with rheumatic heart disease, utilizing a heart sound recording machine simultaneously with an electrocardiograph.

MEDICAL NEWS

JOUR. A. M.
Nov. 25,

Society News.—At a meeting of the Chicago Orthopaedic Society November 10 the speakers were Drs. Henry W. Meyerding, Rochester, Minn., on "Ewing's Tumor (Endothelial Myeloma; Angioblastoma): Diagnostic and Therapeutic Experience in 114 Cases" and Paul H. Dube, "Lesions of Bone Associated with Thyroid Disease."—The Chicago Gynecological Society was addressed November 17 by Drs. Henry Close Hesselstine and George P. Bohlender on "Closure and Subsequent Care in Obstetric and Gynecologic Abdominal Wound Disruption" and Richard W. TeLinde, Baltimore, "Decidua-like Changes in the Endometrium Without Pregnancy."—Dr. Arthur H. Curtis, professor of obstetrics and gynecology, Northwestern University Medical School, will deliver the presidential address before the twenty-fourth annual meeting of the Institute of Medicine of Chicago December 5 on "Some New Features of Gynecologic Anatomy and Related Clinical Problems."

was to receive a bronze plaque as a token of this recognition, was reported.—Dr. George L. G. Cranier, Owosso, was presented with a leather bag by the Shiawassee County Medical Society October 19 in honor of his fifty years in the practice of medicine.

NEBRASKA

Professor Retires.—Dr. Gustave W. Dishong, professor and head of the department of nervous and mental diseases at Creighton University School of Medicine, Omaha, since 1910, has retired after twenty-seven years on the faculty. He graduated from Creighton in 1907. Dr. Dishong has been succeeded by Dr. Ernest Kelley, associate professor in the department. Dr. Kelley also graduated from Creighton in 1907.

Society News.—Drs. James F. Kelly and John J. Freymann, Omaha, addressed the Adams County Medical Society in Ingleside October 4 on "X-Ray Therapy" and "Ovarian Hormones and Their Relationship to the Disturbances of Menstruation and Reproduction" respectively.—Drs. Lynn T. Hall, Omaha, and Paul M. Bancroft, Lincoln, addressed the Custer County Medical Society, Broken Bow, October 17 on pneumonia in adults and in children, respectively.

District Meetings.—The Seventh Councilor District Medical Society held its annual meeting at Fairbury October 19. The speakers were Drs. Charles A. Tompkins, Omaha, on "Diagnosis and Treatment of Functional and Organic Obstruction of the Gastro-Intestinal Tract of Infants"; Harry E. Harvey, Lincoln, "Analysis of Confusing Pelvic Symptoms"; Ralph H. Luikart, Omaha, "Indications and Contraindications for Cesarean Operations," and Clayton F. Andrews, Lincoln, "Surgical Diseases of Childhood." Dr. Arthur L. Miller, Kimball, president of the Nebraska State Medical Association, and Mr. M. C. Smith, Curtis, executive secretary, also made addresses.—Drs. John C. Thompson and Frederick F. Teal Jr., Lincoln, addressed a meeting of the Sixth Councilor District in David City October 16 on the causes and treatment of headache and "Improvement in Position of Fractures After Primary Reduction" respectively.

NEW JERSEY

Personal.—Dr. Marcus W. Newcomb, Browns Mills, was honored at a testimonial dinner at the Community House, Moorestown, recently in recognition of his twentieth anniversary as superintendent of Fairview Sanatorium, New Lisbon. Dr. William J. Carrington, Atlantic City, was the toastmaster and Dr. Edward John G. Beardsley, Philadelphia, the principal speaker. More than 400 attended the meeting.

Society News.—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, addressed the Essex County Medical Society Newark, November 9 on "American Medicine and the National Government."—Drs. Bela Schick, New York, and Nathan Northern New Jersey November 16 on "Newer Treatment Methods for the Respiratory Diseases of Childhood" and "Acute Laryngotracheobronchitis with Membrane Formation" respectively.

NEW YORK

Cancer Day in Nassau County.—Dr. Louis C. Kress, Buffalo, director of the division of cancer control, state department of health, addressed the Medical Society of the County of Nassau, Garden City, October 31, meeting with the Nassau County Dental Society, on "How the State Department Can Help You with Your Cancer Patients." This was the final session of a "Cancer Day" sponsored by the Nassau County Cancer Committee. There was a luncheon session at which Drs. Arthur C. Martin, Garden City, Earle G. Brown, Mineola, and John M. Swan, Rochester, spoke on various aspects of cancer control. At an afternoon session for women Drs. Kress and Norman Treves, New York, were the speakers.

New York City

Dr. Barr to Lecture.—Dr. David P. Barr, Busch professor of medicine, Washington University School of Medicine, St. Louis, will give an address at Cornell University Medical College December 13 under the auspices of the Cornell chapter of Nu Sigma Nu. Dr. Barr's subject will be "The Nature of Obesity."

Medical Dental Meeting.—The Joint Committee of the Organized Medical and Dental Professions announces the ninth annual medical-dental convention to be held December 4 at the Hotel Pennsylvania. At the morning session there will

IOWA

Discussions Instead of Refresher Courses.—The state medical journal announces that round table discussions on maternal and child health will be substituted for the "refresher" courses on pediatrics and obstetrics which have been held throughout the state in the past. Case histories will be used to illustrate points in the discussion and the local audience will be urged to present case histories of its own for review by the round table. The new programs were to begin after November 15.

MAINE

Society News.—Dr. Theodore M. Stevens addressed the Portland Medical Club October 3 on "Pyelitis in Pregnancy" and Velma Pettiner, director of the Portland District Nursing Association, discussed the service and problems of that society in Rockland October 3. Dr. Francis C. McDonald, Boston, discussed "Gastro-Intestinal Disturbances in Infancy."—Dr. Lorne C. Montgomery, Montreal, addressed the Oxford County Medical Society October 25 on pneumonia.—The Penobscot County Medical Society was addressed October 17 in Bangor by Dr. Paul D. White, Boston, on "Heart Diseases."

MICHIGAN

New Administrator for Battle Creek Sanitarium.—Dr. John E. Gorrell, medical director of the Blodgett Memorial Hospital, Grand Rapids, has been appointed administrator of the Battle Creek Sanitarium, Battle Creek. Dr. Gorrell graduated at Northwestern University Medical School, Chicago, in 1930.

Pneumonia Serum Available.—Antipneumococcus serum for the treatment of types I and II pneumonia will again be distributed free to physicians during the 1939-1940 pneumonia season, according to the state department of health. The serum will be available from fifty-two distributing centers throughout the state in addition to thirty branch distributing centers in full time county and city health departments. Typing service will be available at 146 stations in addition to service available from the state department of health laboratories at Lansing, Grand Rapids, Houghton and Powers.

Graduate Conferences.—The fall graduate conferences of physicians sponsored by the Wayne County Medical Society, the Wayne University College of Medicine, the Detroit Tuberculosis Sanatorium and the Detroit Department of Health started November 22 with Dr. Sidney D. Kramer of the division of virology of the state department of health, Lansing, discussing "Virus Diseases." The remaining lectures in the series are:

Dr. John Alexander, Ann Arbor, November 29, Collapse Therapy in the Control of Tuberculosis.
Dr. Ward F. Seely, Detroit, Management of Hemorrhage in Late Pregnancy.
Drs. Henry Cook, Flint, and Clarence D. Selby, Detroit, December 13, Industrial Hygiene in Automotive Manufacturing.

Personal.—Dr. Fred T. Andrews, formerly of Kalamazoo, has been selected as health officer for Bay County, effective October 9.—Dr. Edward G. McGavran, Hillsdale, has resigned as director of the Hillsdale County department of health to devote his time to research. It is reported.—Dr. Dean C. Burns, medical director of the Little Traverse Hospital, Petoskey, has been appointed a member of the state tuberculosis commission. Dr. Burns was recently chosen by residents of the city as the leading citizen of Petoskey and

be a symposium on "Inefficient Mastication—Its Development, Effects and Treatment" by Max J. Futterman, D.D.S., Dr. Albert F. R. Andresen and Clyde H. Schuyler, D.D.S. In the afternoon there will be a clinical meeting followed by a demonstration by a group from the Kings County Hospital.

Dr. Neumann Dies.—Dr. Heinrich Neumann, for many years a distinguished specialist in diseases of the ear in Vienna, died in New York November 6, aged 66. Dr. Neumann was a native of Hungary and took his medical degree from the University of Vienna in 1898. He was appointed to the faculty of the university in 1919 and served until 1938. He came to the United States last spring to work on the refugee problem with the American Jewish Joint Distribution Committee, the *New York Times* reported.

Medal Awarded to Dr. Wood.—The New York City Cancer Committee at its annual dinner November 2 awarded the 1939 Clement Cleveland Medal to Dr. Francis Carter Wood, director of the Institute of Cancer Research at Columbia University College of Physicians and Surgeons. The award was made in recognition of Dr. Wood's work as chairman of the New York World's Fair Cancer Exhibit, sponsored by the city committee. Mrs. Robert G. Mead, who founded the award in 1937 in memory of her father, made the presentation and directed attention to Dr. Wood's work with the American Society for the Control of Cancer and as president of the recent International Cancer Congress in Atlantic City. A special foreign award of the Cleveland Medal was made earlier this year to Mlle. Eve Curie, daughter and biographer of Marie Curie.

Code on Work Relations in Hospitals.—The Greater New York Hospital Association recently adopted a code of employee relations in which it asserted the right of voluntary hospitals to discharge employees "without intimidation or interference when in the judgment of the management such course is in the interest of the welfare of the patients and efficiency of the institution." The association agreed that employees should be free to join any lawful organization but declared that employment should not be made dependent on membership or nonmembership in any group. The statement also pointed out that, although hours of work should not exceed a reasonable maximum per day or week, emergent situations may require longer periods in some departments and that the peculiar nature of hospital work makes it difficult to adhere to time schedules such as obtain in industry.

NORTH DAKOTA

Personal.—Dr. Cedric Northrop, Portland, Ore., has been appointed superintendent of the North Dakota State Tuberculosis Sanatorium, San Haven, to succeed Dr. George Alfred Dods.

New Members of State Medical Board.—Drs. Paul H. Burton, Fargo, and William F. Sihler, Devils Lake, have been appointed to the state board of medical examiners. They succeed Drs. Archie D. McCannel, Minot, and Albert W. Skelsey, Fargo, whose terms expired. Dr. George M. Williamson, Grand Forks, was reappointed.

OHIO

Brush Foundation Affiliated with Western Reserve.—The trustees of Western Reserve University and of the Brush Foundation have entered into an agreement by which the studies on human growth, development and sex initiated by the late Dr. T. Wingate Todd for the Brush Foundation and other foundations as well as future studies sponsored by the Brush Foundation will be conducted through the university's school of medicine. William W. Greulich, Ph.D., research associate in anatomy and physical anthropology at Yale University School of Medicine, New Haven, Conn., has been appointed director of the foundation and professor of physical anthropology and anatomy in the department of anatomy in the medical school.

OREGON

Annual Registration Due December 1.—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to register annually on or before December 1 with the secretary of the Board of Medical Examiners and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days, or part thereof, of default and his failure to reregister within ninety days after December 1 is a misdemeanor.

PENNSYLVANIA

Personal.—Dr. Ezra Pope Dickinson, St. Michael, has been appointed medical director of Cambria County, succeeding Dr. James J. O'Connor, Barnesboro. Dr. William T. Davis, Scranton, has been appointed medical director of Lackawanna County, succeeding Dr. John J. Bendick, Olyphant.

Philadelphia

Society News.—A symposium on rheumatic fever was presented before the Philadelphia Rheumatism Society November 16 by Drs. Paul H. Parker, Jenkintown, Pa., Louis B. Laplace and William D. Stroud. A symposium on anesthesia was presented before the Philadelphia Laryngological Society November 7 by Drs. Helen E. Riggs, Albert Behrend and Edward W. Beach. Lieut. Col. James E. Ash, curator of the Army Medical Museum, Washington, D. C., addressed the Pathological Society of Philadelphia November 9 on "Tumors of the Urinary Bladder." At a meeting of the Philadelphia Psychiatric Society November 10 the speakers were Drs. Morris W. Brody and Herbert Freed on "Compulsive Phenomena with Associated Oculogyric Crises"; Paul Sloane, "Psychotherapy; Principles Underlying the Choice of Therapy," and James J. Waygood, "Treatment of Milder Psychoses."

Program of College of Physicians.—The coming scientific lectures of the College of Physicians of Philadelphia for the current season include the following:

Dr. Howard T. Karsner, Cleveland, Certain Ovarian Tumors Associated with Sexual Endocrine Dysfunction, December 6.
Dr. Charles Armstrong, Washington, D. C., Recent Developments in Central Nervous System Virus Infections, with Special Reference to Lymphocytic Meningitis and Poliomyelitis, January 3.
Dr. Tom D. Spies, Cincinnati, Clinical and Laboratory Studies on the Avitaminoses, with Special Reference to Nicotinic Acid, Thiamin and Riboflavin, February 7.
Dr. Alvin F. Coburn, New York, Factors in the Initiation of Rheumatic Activity, March 6.
Dr. Baldwin H. E. W. Lucke, Philadelphia, Tumors in Cold-Blooded Animals, Their Significance in the Experimental Investigation of Cancer; and Dr. Joseph McFarland, Philadelphia, The Pathological Diagnosis of Cancer in Man, April 3.

Three lectures for the public are included in the program: November 17, Dr. Oliver H. P. Pepper on "Medical Problems of Advancing Age"; January 19, Dr. Jacob Parsons Schaeffer, "The Human Constitution and Some of Its Problems," and April 12, Dr. William Edward Chamberlain, "The X-Ray as an Aid in Diagnosis."

Pittsburgh

Academy Celebrates Golden Anniversary.—The Pittsburgh Academy of Medicine celebrated its fiftieth anniversary with a dinner November 11. The speakers were Drs. Nathan B. Van Etten, New York, President-Elect of the American Medical Association; Charles H. Henninger, Pittsburgh, president of the Medical Society of the State of Pennsylvania, and Henry T. Price, president of the Allegheny County Medical Society. The oldest living fellows of the academy are Drs. Ewing W. Day, Provincetown, Mass., Theodore Diller and Joseph M. Douthett. No original charter members are living. The academy is especially distinguished for its library of 20,000 volumes. It acquired the Pittsburgh Medical Library Association's volumes in 1896; in 1917 it moved into its own building and has employed a full time librarian since 1922.

SOUTH DAKOTA

Personal.—Dr. George J. Frazier, Gregory, was presented with the 1939 Indian achievement medal by the Indian Council Fire at a meeting in Chicago September 22. Dr. Frazier, a full blooded Indian, according to newspaper reports, has been in the Indian service for twenty-five years and at present serves among the Sioux of South Dakota.

TEXAS

Public Health Meeting.—Dr. John W. E. H. Beck, Austin, was elected president of the Texas Public Health Association at the annual meeting in Galveston in October. Among the speakers were Drs. Holman Taylor, Fort Worth, secretary, State Medical Association of Texas, on "Cooperative Responsibility in the Development of Our Public Health Program"; Preston Hunt, Texarkana, president-elect of the state medical association, "Building Sound Public Health Policy"; Shirley S. Bowen, Galveston, "The Physician's Responsibility for Health Education"; John W. Spies, dean, University of Texas School of Medicine, "Public Health in the Medical Curriculum"; Erval R. Coffey, U. S. Public

Health Service, "Practical Problems of Public Health," and Mr. John Carmody, administrator of the Federal Works Agency, Washington, D. C., "The Meaning of Public Health to the Nation."

VERMONT

New Dean at Medical College.—Dr. Hardy A. Kemp, professor of bacteriology and preventive medicine at Baylor University College of Medicine, Dallas, Texas, has been appointed dean of the University of Vermont College of Medicine, Burlington. Dr. Kemp succeeds Dr. James N. Jenne, who died Sept. 9, 1937. During the period since Dr. Jenne's death Dr. Ernest H. Buttles, professor of pathology and bacteriology, has been chairman of a committee of administration for the school. Dr. Kemp, who is 37 years old, graduated from St. Louis University School of Medicine in 1926 and went to Baylor in 1928 as associate professor of bacteriology and hygiene. Among new members added to the faculty are the following:

Dr. Bird J. A. Bombard, Burlington, associate professor of clinical surgery.

Dr. Aymer S. C. Hill, Winooski, assistant professor of clinical medicine.

Dr. Arthur R. Hogan, Burlington, assistant professor of clinical surgery.

Dr. Peter P. Lawlor, Burlington, assistant professor of otolaryngology and rhinology and clinical instructor in ophthalmology.

Dr. Wilhelm Raab, formerly of Vienna, assistant professor of clinical medicine.

WEST VIRGINIA

Changes in State Health Department.—Dr. John F. Cadden, director of the bureau of industrial hygiene of the state department of health, has resigned to become medical director of the plant of the American Viscose Corporation at Roanoke, Va. Dr. Charles N. Scott, director of the bureau of venereal disease, has accepted a similar position with the viscose plant at Nitro. Dr. John B. Hozier of the U. S. Public Health Service, recently lent to the health department to develop the venereal disease program, was named to succeed Dr. Scott. Dr. Thomas H. Blake, director of county health work, resigned to enter private practice at St. Albans. Dr. Bruce H. Pollock, Point Pleasant, has been appointed to succeed Dr. Blake.

Society News.—Dr. Allen F. Voshell, Baltimore, gave an address before the Ohio County Medical Society, Wheeling, November 3 entitled "A Discussion of Fracture Fundamentals and Errors."—Dr. Stanley Weinstein, Huntington, addressed the Cabell County Medical Society, Huntington, October 12 on the "Glandular and Hormone Treatment of the Menopause." The society adopted a resolution favoring the proposed creation of a national department of health with a cabinet portfolio.—Dr. Thomas K. Laird and Robert Harold Jones, Montgomery, addressed the Fayette County Medical Society, Montgomery, October 17, on "Etiology, Symptomatology and Treatment of Pelvic Infections in Women" and "Value of Gastroscopic Study" respectively.—Dr. Harold W. Jacox, Pittsburgh, addressed the Kanawha Medical Society, Charleston, October 10 on "Lymphoblastoma."—At a meeting of the Lewis County Medical Society in Weston October 10 the speaker was Dr. William R. Goff, Parkersburg, on "Diagnosis of Thyroid Conditions."—Dr. Hugh W. Macmillan, Cincinnati, who is also a dentist, addressed a joint meeting of the Logan County medical and dental societies in Logan November 8 on "Deep Abscesses of the Neck of Dental Origin."

GENERAL

Special Society Election.—Dr. Charles W. M. Poynter, Omaha, was chosen president-elect of the Association of American Medical Colleges at its annual meeting in Cincinnati October 23-25 and Dr. Russell H. Oppenheimer, Atlanta, Ga., was installed as president. Dr. Eben J. Carey, Milwaukee, was elected vice president and Dr. Fred C. Zapffe, Chicago, reelected secretary. Next year's meeting will be at the University of Michigan, Ann Arbor.

Another Swindler.—A man giving the name of Folger and claiming to represent Folger and Company, St. Louis, recently collected money in advance from a Chicago physician for an order of medical supplies. He claimed to be an expert on repairing blood pressure apparatus and stethoscopes. On investigation it was found that Folger and Company do not handle medical supplies and that this firm has no representative in Chicago and no representative named Folger. This man is about 55 years old, 5 feet 4 inches tall, weighs about 135 pounds and is well versed in medicine, according to the report.

Nobel Prize Goes to Professor Lawrence.—The 1939 Nobel prize for physics was awarded November 9 to Ernest O. Lawrence, Ph.D., professor of physics and director of the

radiation laboratory, University of California, Berkeley, for invention and development of the cyclotron and results obtained with it, especially in disintegration of the atom and production of artificially radioactive elements. Dr. Lawrence was born in Canton, S. D., in 1901. He graduated at the University of South Dakota in 1922, receiving an honorary degree of doctor of science in 1936. Yale University awarded him the degree of doctor of philosophy in 1925 and an honorary science degree in 1937. Prior to joining the staff of the University of California he was associated with Yale.

Symposium on Blood, Heart and Circulation.—The Section on Medical Sciences (N) of the American Association for the Advancement of Science announces that its sessions at the Christmas meeting in Columbus, Ohio, December 27-30, will be devoted to a symposium on the blood, heart and circulation. Topics for the separate sessions are: blood, physiology of coronary blood flow, pathology of the coronary circulation, cardiac failure, hypertension, heart and circulation in special territories. Twenty-eight papers are listed on the program. In addition, Dr. Carl J. Wiggers, Cleveland, vice president of the section, will deliver his official address on "The Physiology of Coronary Blood Flow" and the Theobald Smith Award in Medicine is to be awarded to Dr. Albert B. Sabin, Cincinnati, who will speak on "Constitutional Barriers to Involvement of the Nervous System by Certain Viruses."

Lalor Foundation Awards Available.—Applications are invited for the fourth series of awards by the Lalor Foundation for fundamental research in chemistry. The awards are open to men and women for work anywhere. The Ph.D. degree or training equivalent thereto is a requirement. Final selections will be based on the previous training, demonstrated competence and promise of the candidates in their fields of work. Preference will be given for part of the awards to candidates directing their research toward applying the principles and discoveries of physical and organic chemistry to problems in the fields of biochemistry and chemotherapy. In the case of awards of this kind, renewals of the grants for an additional year will be favorably considered. Time to be spent in acquiring training in the medical studies necessary for a thorough understanding of the clinical aspects of the subjects will be considered acceptable as a part of the plan of the work of the candidate. Individual awards will range between \$1,800 and \$2,500 or according to the special needs of the candidate. Inquiries and requests for application forms should be addressed to C. Lalor Burdick, Secretary, Lalor Foundation, Wilmington, Del. Applications must be in the hands of the secretary by December 31. Appointments will be announced early next March.

Council on Problems of Alcohol.—A new executive committee of the Research Council on Problems of Alcohol announced at a recent meeting a broad program for attacking the diseases of alcoholism. Dr. Karl M. Bowman, director of psychiatry, Bellevue Hospital, New York, chairman of the committee, announced three grants of financial aid to the organization. The Carnegie Corporation has appropriated \$25,000 for a survey of work done to date on the effects of alcohol on the individual, a project sponsored by the department of psychiatry, New York University College of Medicine, under the supervision of Dr. Norman H. Jolliffe, associate professor of medicine. The American Philosophical Society is financing a study of the toxic factors in alcoholism conducted at the New York Psychiatric Institute under the direction of Dr. George A. Jervis. In addition, the Dazian Foundation for Medical Research has granted funds for research on the role of alcohol in liver cirrhosis, a project initiated by New York University College of Medicine. Members of the new executive committee are:

Forest R. Moulton, Ph.D., Washington, D. C., permanent secretary, American Association for the Advancement of Science.

Dr. Winfred Overholser, superintendent of St. Elizabeths Hospital, Washington.

Dr. Lawrence Kolb, chief, division of mental hygiene, U. S. Public Health Service, Washington.

Dr. Nolan D. C. Lewis, professor of psychiatry, Columbia University College of Physicians and Surgeons, New York.

Hans T. Clarke, D.Sc., professor of biochemistry, Columbia University, New York.

Luther H. Gulick, Ph.D., director, Institute of Public Administration, New York.

Mr. Leonard Harrison, director of the Committee on Youth and Justice, New York.

Mr. Austin H. MacCormick, commissioner of correction, New York.

Albert T. Poffenberger, Ph.D., professor of psychology, Columbia University, New York.

Robert W. Searle, D.D., general secretary of the Greater New York Federation of Churches, New York.

Mr. Albert W. Whitney, consulting director, National Conservation Bureau, New York.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 25, 1939.

The Decadence of Science Under Nazi Rule

Sir Thomas Holland, principal and vice chancellor of Edinburgh University, presiding at a graduation ceremony, predicted a degeneration in German military efficiency as a result of neglect of scientific research, which was evident in the last six years. Sir Thomas, who is a past president of the Institution of Mining and Metallurgy, said that during those years German universities turned out from their research laboratories a gradually diminishing stream of products. Six or seven years ago no scientific man in the world would have dared to pass over the publications of the research institutions of Germany. Not only were they great in volume but their quality was of a kind that led the world. Today these volumes of output have diminished to small fragments of their former size, and their quality is negligible. One can predict from this fact alone that the neglect of fundamental truth for its own sake must be followed by degeneration in technical efficiency. What is less important possibly, but immediately important to everybody in Europe, is that this neglect certainly will be followed by degeneration in military efficiency. It is now or never for Germany, even from the military point of view. Referring to the suggestion that Germany itself might soon save the situation, Sir Thomas said that it was easy to destroy a great structure but that it took many years to build another like it. Only the very youngest in the room would live to see the time when German universities would be restored to their old position in the intellectual world.

Deaths from Road Accidents Doubled by the Black Out

The restrictions on street lighting rendered necessary by the danger of air raids has doubled the fatalities from road accidents. In the House of Commons the minister of transport reported that the number of persons who died during September as a result of road accidents was 1,130 against 554 in September a year ago. Information as to the number injured was not available. Since the first days of the emergency, efforts had been made to achieve the maximum possible safety in road conditions consistent with demands of defense against attacks from the air. The public could help to secure a reduction in accidents by increased care on the roads and refraining from the use of automobiles after dark except when absolutely necessary. Many accidents occurred to pedestrians crossing the road, as the drivers could not see them before their cars struck them. It is suggested that pedestrians should wear or carry something white or of a light color and walk on the left side of the pavement. The "Safety First Council" described the foregoing figure as the most serious statement on road accidents ever made in Great Britain. War time conditions have prevented the compiling of the figure for the injured. If the proportion to killed remains the same as before—a reasonable assumption—more than 40,000 persons must have been injured on the roads this September, 10,000 of them seriously.

The Danger of Radium Dispersal by Air Raids

The Emergency Measures Committee of the National Radium Commission has issued a memorandum on the danger of radium dispersal by aerial bombardment, by A. R. Greatbatch, of the Research Department of the Woolwich Arsenal. He points out that in considering dangers from aerial bombardment attention must be given to the disruptive action of a high explosive bomb on radium containers and the probable dispersion of radium dust over a wide area. Unprotected radium needles would almost certainly be disrupted and the contents scattered

by the blast from the explosion of a 500 pound bomb within a range of 20 feet. Any envelop surrounding the needle would afford some protection. A reasonable protection would be given by a steel container 3 inches thick. The danger from fragmentation is of a different nature. The radium container may be struck by one of the thousands of fragments hurled by the force of the explosion at double or even treble the muzzle velocity of a rifle bullet. This danger may extend to more than a hundred feet from the bomb. A direct hit by a fragment within this area would shatter a container unless heavily protected in the manner described. The protective value of the building housing the radium must be considered. It should be related to the fact that bombs dropped from a height of 10,000 feet or more can penetrate 5 feet of concrete and 30 feet of earth. Thus for complete protection from a 500 pound bomb the radium should be covered by more than 30 feet of earth. The recommendation that radium should be sunk 50 feet in the ground (which already has been done) will therefore ensure safety from radium dispersal in all circumstances, including a direct hit.

Casualty Evacuation Trains for Civilians

The vast organization formed for the defense of the civilian population against air raids has been described in previous letters. Every possible contingency, even to the disposal of the dead, has been the subject of careful planning. A new example is trains specially adapted for the evacuation of air raid casualties from hospitals in dangerous areas to base hospitals outside them. There are twenty such trains in London, eight in the English provinces and two in Scotland. Their crews consist of one medical officer, one hospital train officer, three trained nurses and ten auxiliary nurses. Each train is made up of nine parcel vans converted to take thirty stretchers in each van. Brackets have been fixed to the sides of the vans, and the stretchers are in two tiers. There is a coach with a kitchen attached, so that the patients can have hot meals during the journey. All the crews have been working on their trains for some time, so that they now form organized teams.

Adaptation of the British Pharmacopeia to War Conditions

The British Pharmacopeia Commission is engaged on modification of the pharmacopeia to the exigencies of war. The strain imposed on the medical services of the country renders necessary the utmost economy in the prescribing of drugs. At the invitation of the Ministry of Health, the Medical Research Council has formed a therapeutic requirements subcommittee to advise the ministry and the medical and pharmaceutical professions on economy in the use of drugs. When there are several remedies for a particular disease it may be desirable to concentrate on the manufacture of a particular one. Difficulties may arise from the fact that the raw materials for the manufacture of many remedies have to be imported from abroad or because war conditions may cause an abnormal demand for certain drugs.

The Conveyance of Disease by Airplane

At the Royal Society of Medicine, Air Commodore H. E. Whittingham said that journeys by air from countries where the major infectious diseases—cholera, plague, smallpox, typhus and yellow fever—are endemic to uninfected countries are now usually completed well within the incubation periods of these diseases. The health control of traffic is based on the International Sanitary Convention for Aerial Navigation, 1933, which specifies the maximum measures which may be imposed but leaves their application to each country, the aim being to make the regulations as uniform as possible, to lessen inconvenience to passengers and cause the minimum delay. Each government has drawn up its own regulations for the sanitary con-

trol of aviation. In the United Kingdom aircraft are permitted to land only at the authorized airdromes. A sanitary airdrome is designated "a local area" if it is beyond all probable risk of contamination from without. No one must enter or leave it without official permission. If a death, other than by accident, occurs on an aircraft arriving from abroad, or a case or suspected case of infectious disease (other than tuberculosis or venereal disease), the craft must notify the airdrome medical officer or customs officer, preferably by wireless, before arrival. Infected aircraft or those coming from places infected with cholera, plague, smallpox, typhus or yellow fever, or those with rodents dying aboard, must not discharge passengers, crew or cargo until the medical officer has inspected them and declared them free from infection. The usual procedure is to isolate in a hospital persons showing evidence of infection, while the contacts may be liberated after giving names and addresses of destination and they will then be under the surveillance of the local health officer. Adequate vaccination against smallpox or inoculation against cholera or yellow fever exempts from isolation. In cases of infection the aircraft is disinfected. In aircraft from the tropics and subtropics disinsection is performed to prevent the introduction of mosquitoes carrying the germs of yellow fever, dengue or malaria. If there is a case of cholera or the aircraft has come from a cholera infested area, fish, fruit and vegetables must not be unloaded.

YELLOW FEVER

Special precautions are taken against yellow fever, as the mosquito vector (*Aedes aegypti*) is prevalent in the tropics and subtropics. The fear of spread to India by air traffic is considered so great that the government has taken additional precautions. Passengers from yellow fever areas in Africa are not permitted to enter India until nine days has elapsed since their departure, and aircraft are not permitted to fly direct to India from such areas unless in possession of a certificate from the Egyptian Quarantine Board stating that the aircraft has been disinfected. In common with the Dutch East Indies and the Sudan, India prohibits the importation of yellow fever virus even for research purposes. The danger is considered so great that the following precautions are recommended: 1. Provision of anti-malarial airdromes in all yellow fever districts. They have been established at Kano, Malakal and Khartoum. The last is not in a yellow fever area but is a clearing place for air traffic. 2. A campaign against *Aedes aegypti*. This has already produced a marked decline along the air routes of Africa. 3. Possible requirement that intending passengers may be required to go into isolation for six days before embarkation. In Nigeria seven days' notice of flight is demanded, so that it can be decided whether quarantine in a mosquito proof hut is necessary. 4. A change of aircraft during journeys, which lessens the risk of transporting infected insects beyond a certain point. 5. The destruction of mosquitoes in aircraft, which has occupied the attention of experts in various countries. Deskito, a water-soluble pyrethrum concentrate, diluted from ten to fourteen times, is used as a spray by Imperial Airways. 6. Inoculation against yellow fever of all who intend to travel by air through yellow fever districts.

Little Traffic in Dangerous Drugs in Great Britain

The report on the traffic in opium and other dangerous drugs in Great Britain, which has been presented to the League of Nations by the government, deals with the year 1938 and states that drug addiction is not prevalent. The number of persons known to the central office during the year as addicted to narcotics was 519—246 men and 273 women. Of these 134 were physicians, two were dentists, five were pharmacists and two were veterinary surgeons. The percentages of addiction to different drugs were morphine 78.7, diacetylmorphine 13.2, medicinal opium 0.4, dihydromorphinone 0.6. During the year

three physicians, six pharmacists and one veterinary surgeon were convicted of offenses against the Dangerous Drugs Act. There was no evidence of any organized illicit traffic. Such cases of illicit import as were discovered were individual attempts, usually by oriental seamen, to bring in small quantities for their own use or that of compatriots resident here. Two attempts to smuggle in small quantities of prepared opium by means of the newspaper post were discovered. No single seizure of opium exceeded 12 ounces.

The Blood Tests Bill

The report of the House of Lords select committee on the bastardy blood tests bill recommends that it should become law. The committee is satisfied that the risks of error have been reduced to negligible proportions and that the tests would prevent injustice. Replying to the criticism that to make it mandatory on the court to order a blood test would be an interference with the liberty of the subject, the committee feels that, in view of the possible injury to reputation, these cases require special treatment. An "approved person" should be nominated by the court to take tests. He should be a physician who is also a pathologist, but blood samples for the test could be taken by a physician who is not an approved person. In view of possible nervousness on the part of the woman, this physician should, if possible, be her regular medical attendant. In all cases in which an applicant refuses to undergo a blood test, her application should be dismissed.

Evacuation of the Wounded by Air

Air forces will play a greater part in this war than in any previous one, and a new development, which has already begun, is evacuation on a large scale of the wounded by air. The British air force has in France complete units for the evacuation to England of casualties and patients with all possible speed by air. Up to the present all the casualties have been evacuated in this manner. In addition the medical services have a complete system whereby in an emergency the blood transfusion units can be carried by air right into the front line. If necessary, transfusion can be performed while the wounded man is being carried in air transport.

Occupational Diseases of the Skin

During the sessions of the Journées internationales de pathologie et d'organisation du travail, held last May in Paris, the official report of which has just been published, Flandin and Rabeau presented a paper on occupational dermatoses based on 1,000 cases among workers of different trades. Occupational diseases of the skin constitute from 40 to 70 per cent of all occupational diseases. Diseases of the skin are among those which incapacitate longest for work. Their etiology is often obscure. In some cases diseases of the skin are clearly caused by the occupation alone; in most other cases it is difficult to determine the particular toxic, infectious, mechanical or allergic agent. In other cases cutaneous diseases of a mycotic, nutritional or diathetic nature may be modified by scratching or by local infections, syphilis, diabetes, tuberculosis, lichen, ichthyosis and so on. In this confusion, recourse is finally had to cutaneous tests, which require much time. However, improvement in technique will no doubt bring about a shortening of the time. One of the great difficulties in applying these tests is the large number of allergens that have to be considered. Flandin and Rabeau described their modification of Bloch's technique. They stress the need of attention to detail as well as the experience required for the correct interpretation. The susceptibility of individuals changes in the course of the years and even with

the seasons. There are also sensitization thresholds, activating substances and physical factors such as heat, humidity and light by which allergy is more or less aided in its evolution. Fifty per cent of cutaneous diseases are purely exogenous; 30.35 per cent in men and 19.74 per cent in women are designated as seborrheas, a term used with reservation because of its possible provisional nature; 26.28 per cent of cutaneous diseases in men and 25.28 in women are of bacterial or mycotic origin. Substances used for cosmetic purposes cause 20 per cent of eczemas in all occupations.

Trachoma and Rickettsia

At a meeting of the Académie de médecine, Georges Blanc, R. Pages and L. A. Martin brought to the support of the analogies invoked between trachoma and Rickettsia infections the results of new attempts to transmit trachoma to *Macaca sylvanus*, an animal especially sensitive to the disease. They were able to bring about five transmissions from monkey to monkey and thereupon from monkey to man and from man to monkey, the trachoma agent losing nothing of its virulence in the course of its successive inoculations. The infections induced in man by the virus of the baboon is of the acute type observed by all investigators in the infection provoked by the human virus. Of the three types of Rickettsia so far described in trachoma infection, that of Busacca-Poleff, that of Cuénod-Nataf and that of Foley-Parrot, only the last one was found by Blanc and his collaborators. Prowazek's bodies were frequently but not always observed in the experimental trachomas which they caused. They appeared between the twentieth and the thirtieth day and lived only a few days. Although they have the appearance of "parasites," the fact that they are relatively rare in trachomatous monkeys invites caution in speculating on their pathogenic role.

The Epidemicity of Acute Rheumatic Fever

Blechmann, at a recent session of the Société médico-chirurgicale des hôpitaux libres, reported the results of his observations on acute rheumatic fever, a subject proposed by the military health service for further study.

Epidemicity is one of the characteristics which render acute rheumatic fever a disease entity. Its cause is not yet known, or at least there is no proof of the part played by the different germs so far isolated. However, cases of familial rheumatism are sufficiently numerous and indicate a hereditary predisposition or suggest a direct transmissibility. Besides, several outbreaks, evidently of an epidemic character, have been reported, notably during the World War, both in military circles and in isolated groups in which soldiers were in prolonged casual contact with civilians. The argument often advanced for the seasonal nature of the disease cannot be entertained. The fact that the infection is not fatal and that its mechanism is not known does not constitute an argument against its infectiousness. Its transmission seems to require a direct and prolonged contact. The point of entry seems to be the pharynx. There is, at least according to army medical statistics, a close parallelism between the curves of acute rheumatic fever and angina, which is often considered the only symptom of it. The connection between acute rheumatic fever and scarlet fever is still clearer. The effect of salicylates on the manifestation of scarlet fever and rheumatism emphasizes the community of origin between the two maladies. Conditions such as humidity and overfatigue clearly are to be reckoned among the inducing causes. Billings and Rosenow, on the other hand, stress the role of focal infections of a buccal nature. Many authors ascribe this rheumatic infection to a variety of streptococci such as *Streptococcus viridans* or *Streptococcus haemolyticus*. Others have described numerous germs or associations of germs the specificity of which has not yet been demonstrated.

BERLIN

(From Our Regular Correspondent)

Oct. 25, 1939.

War Closes Some Universities

All universities have been closed except those of Berlin, Vienna, Munich, Leipzig and Jena. According to reports, these five have been selected to continue their teaching and research functions and to maintain their departments of physical culture unimpaired. Several technical schools and art schools also will remain open. The other universities will accelerate and complete their examinations before closing. Students disqualified for military service and those not yet called to the colors are required to continue their academic studies at once. Medical students who have passed the medical examinations but have not served their year of training in the clinics, a training that is still obligatory and a prerequisite to full medical recognition, are to be granted their diploma at once. The same regulation applies to druggists. The *National-Sozialistische Parteikorrespondenz* now issues a special wartime service which it calls "The Inner Front." In this war time service Dr. Conti, state leader of physicians, has announced that one third of the 38,000 physicians practicing in Germany have been mobilized for military purposes. A noticeable shortage of physicians has set in since the discriminatory policy against Jewish physicians was enforced. This shortage has in no wise been corrected. The remaining two thirds are to be distributed equally over the rest of the country. All physicians with a private practice are required to assume duties that may be assigned to them, such as those connected with the sick funds and with public hygiene and health. To prevent financial discriminations, physicians who previously were not admitted to sick fund and public health practice may now, and under certain conditions are required to, serve where the sick fund medical association assigns them. Moreover, the number of practicing physicians has been enlarged by granting medical students completing their last semester their diploma. In this way the government is able to make 2,400 "physicians" available at once who are to assist in military and other hospitals and thus make it possible to release older physicians for home service; many married female physicians who were prohibited from practicing during the last years have offered their services and are now in active practice.

Besides, hospital services of an auxiliary nature have been organized in sufficient number according to Dr. Conti's announcements. Official appointments of physicians have also been made for the "liberated and occupied" districts and the necessary measures inaugurated to prevent the occurrence of epidemic diseases. Dr. Conti admitted that, because of the withdrawal of many physicians from ordinary life and their assignment to military needs, medical services would here and there be curtailed. He advised that physicians be called only if really needed and that patients consult the physicians as much as possible at their office.

Physicians also may establish themselves at new locations only with official permission. This measure has been taken to protect the interests of physicians called to the front. No permanent certificate is therefore granted for sick fund practice during the continuation of the war.

The use of automobiles, prohibited during war times without official permission, is conceded to practicing physicians. Official permit is signaled by a red corner on the automobile plates issued.

Membership in the sick funds is assured during war times and members are relieved of paying assessments. Their needs are taken care of at the front by military physicians, while their families continue to enjoy the medical service provided by the sick funds.

Hospitalization Figures for 1937

According to a report just issued, the average proportion of hospital beds in the combined hospitals of the nation at the end of 1937 was 92.7 per cent to 10,000 inhabitants, as compared with 92.2 per cent in 1936 and 92 per cent in 1935. Likewise the number of patients treated in the combined hospitals increased by about 245,000, totaling about 5,400,000, equivalent to 799.3 to 10,000 inhabitants. The number of hospitalization days increased from 180,000,000 to 186,000,000, equivalent to 3.1 per cent, although the days for which the individual patient was hospitalized fell, on the average, from 34.9 to 34.3 per cent; in 1935 the percentage stood at 35.2. The higher figures for hospital services in 1937, as compared with those of 1936, are to be ascribed to increased patronage and not to a prolonged hospitalization of the average patient. The average in percentages between 1932 and 1937 is represented by 71.6 as against 81.1. Individual figures vary according to location, size of the hospital, time of the year and the type of the hospital. On an average, about 510,000 beds were in daily use in the combined hospitals and 250,000 in the general hospitals. The mortality rate for all hospitals was the same as that for the preceding year, namely 4.9 per cent. Of every 100 deaths occurring in Germany in 1932, 26.7 per cent occurred in hospitals; in 1937 the number rose to 28 per cent. Hospitalized obstetric cases increased by 8 per cent over those of the preceding year. Artificially induced miscarriages in hospitals had decreased in 1936 by about 28 per cent over those of 1935, manifestly in consequence of a more rigorous diagnosis; in 1937 there was a further decrease of 16.4 per cent. The frequency of births in hospitals showed a further increase, as discernible from these figures: 251 per thousand in 1935, 270 in 1936 and 293 in 1937.

Tuberculosis and the Army

Serial x-ray examinations have been increasingly used in Germany in the case of factory employees and members of formations. They are also employed largely in the army. Detailed information is now furnished by Surgeon Major Dr. Deist in the *National-Sozialistische Parteikorrespondenz*. Serial x-ray examinations were begun in the army in 1931. In 38,041 tests there were found sixty-four cases of active (0.168 per cent) and sixty-six of inactive pulmonary tuberculosis (0.74 per cent). In the old national army of 100,000 men the greatest number of active cases was not discovered in the first year but in the fifth and ninth years of service. However, since the introduction of general military service the picture has undergone some modifications so that men in the first and second years of service are somewhat considerably involved. Besides irradiations, prophylactic roentgenograms are to be taken of every recruit immediately on admission into the army. A medical check-up is made in his second year with special attention given to those with inactive or suggestive indications. On discharge from military service at the end of the second year another prophylactic test is made. Regular army soldiers are to be given x-ray examinations annually. These plans and measures may not be carried out during the present war conditions but deserve attention for the principles of social service involved.

Measures Governing Alcohol Control

Official regulations dealing with alcohol control were reported in THE JOURNAL September 16, p. 1144. The new regulations, designed to prevent traffic accidents, relate to employees of street cars and require that every employee report for duty in a sober condition; that is, free from the effects of alcohol or other stimulants. The consumption of alcohol is prohibited not only during working hours but while the employee gets himself ready or performs official errands. New regulations also prohibit any reference to the effects on health in the advertising of brandy products. Health references prohibited include reference to dietetic effects such as "promoting diges-

tion," "stimulating the appetite," and "beneficial." Pictorial representations of this kind also are banned. Only in case of bitters and liqueurs that possess a sufficiently high content of herb extracts and ingredients of bitters, reference may be made to such an effect in the advertisements; but it must be limited to moderate expressions.

Personals

As reported in THE JOURNAL Dec. 17, 1938, page 2318, Franz Volhard, professor of internal medicine in Frankfurt on the Main, retired at the end of 1938. Prof. William Nonnenbruch, director of the second medical clinic at the German university in Prague, has been appointed as his successor. Nonnenbruch was a pupil of Morawitz, director of the medical clinic in Würzburg at that time. As early as 1917 Nonnenbruch made a reputation by his publication based on observations of kidney diseases in army campaigns. His further work was chiefly in the field of the pathology and clinical studies of kidney diseases and of water metabolism. In 1928 Nonnenbruch was called to Prague, where in addition to medical problems he devoted himself extensively to encouraging young men of German extraction to study medicine. Associate professor Schellong, of Heidelberg, was appointed as his successor at Prague.

ITALY

(From Our Regular Correspondent)

Sept. 30, 1939.

Congress of Medicine and Surgery

The fourth Congresso Medico-Chirurgico of Calabria was held recently; Prof. Rocco Jemma was president.

Prof. Roberto Falcone, who spoke on treatment of fractures, made the following suggestions: 1. In all cases of fracture it is advisable to make a careful x-ray examination in various projections before attempting any maneuver. 2. Anesthesia is indicated in certain cases in order to make an x-ray examination of the fracture, and in all cases to obtain a perfect reduction. 3. Early reduction of the fracture has a favorable influence on the healing process. 4. To apply traction and contra-extension it is advisable to resort to apparatus and special beds, as well as to apply direct traction on the bones in certain cases. 5. The limbs must be relaxed to prevent muscular tension. 6. A perfect coaptation should be maintained as long as necessary and, when indicated, transosseal fixation should be resorted to. 7. If a cast is applied it should have no lining and should not interfere with the functions of nearby muscles and joints. 8. The use of the limb must be regained as soon as possible to prevent muscular atrophy, articular rigidity and edema. 9. Physical therapy can be applied only after the inflammatory reaction has completely disappeared.

Marriages

TAUSBEE B. BEATTY, Margaretville, N. Y., to Miss Merle Virginia Wagon of San Bernardino, Calif., in Warren, Va., September 24.

RICHARD S. BLOOMER, Rockville, Ind., to Miss Betty Ann Glore of Greencastle in Indianapolis, October 28.

HENRY STUART BUREM, Kingsport, Tenn., to Miss Irene Marion Gormley at Johnson City, October 14.

RAY O. FESSEY, Nashville, Tenn., to Miss Louise Earls Scales of Columbia, Tenn., in October.

RICHARD BOXLEY BOWLES, Deltaville, Va., to Miss Elizabeth Billups of Mathews, September 30.

GEORGE NUGIER DES ORMEAUX to Miss Rosa Mary Orr, both of Lafayette, La., October 14.

MARGARET L. MAISOLL to Mr. Richard Newhouse, both of Morristown, Ind., October 26.

HERMAN ANFANYER, New York, to Miss Billie Rose Spencer of Troy, Miss., recently.

Deaths

DEATHS

1979

Foster Kyle Collins * Los Angeles; Medico-Chirurgical College of Philadelphia, 1899; associate professor of surgery, College of Medical Evangelists, and formerly professor of operative surgery; demonstrator and lecturer in surgery, Woman's Medical College of Pennsylvania, Philadelphia, 1901-1910; demonstrator of operative surgery at the University of California Post Graduate School, 1916-1926; member of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; past president of the Los Angeles Surgical Society; served during the World War; attending surgeon to the Hollywood Clara Barton Memorial Hospital, now known as the Presbyterian Hospital-Olmsted Memorial, and the Los Angeles General Hospital; aged 68; died, September 18, of cerebral hemorrhage.

James Harold Borrell * Buffalo; University of Buffalo School of Medicine, 1914; member of the House of Delegates of the American Medical Association, 1937-1939; president-elect and formerly vice president of the Medical Society of the State of New York; past president and treasurer of the Medical Society of the County of Erie; member of the American Urological Association; fellow of the American College of Surgeons; aged 47; member of the staffs of the Sisters Hospital, Deaconess Hospital and Lafayette General Hospital; past president of the staff of the Millard Fillmore Hospital, where he died, September 29, of spontaneous pneumothorax.

George Washington Wales Brewster, Boston; Harvard Medical School, Boston, 1893; member of the Massachusetts Medical Society, American Surgical Association and the New England Surgical Society; fellow of the American College of Surgeons; consulting surgeon to the Massachusetts General and Beth Israel hospitals, Boston, Milford (Mass.) Hospital, Leonard Morse Hospital, Natick, Mass., Brockton (Mass.) Hospital and the Chelsea (Mass.) Memorial Hospital; aged 73; died, September 26.

Harry Jay Brayton * Syracuse, N. Y.; Syracuse University College of Medicine, 1903; associate professor of clinical medicine (tuberculosis) at his alma mater; director of the Onondaga Health Association; superintendent of the Onondaga Sanatorium from 1915 to 1939; consultant in diseases of the chest, Syracuse Psychopathic Hospital and the Syracuse General Hospital; aged 58; died, September 20, of cerebral arteriosclerosis and cerebral hemorrhage.

E. Agate Foster, Patchogue, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1890; member of the Medical Society of the State of New York; president of the Suffolk County Medical Society; bank president; formerly member of the board of education and vice president; at one time mayor; aged 72; died, September 28, of carcinoma of the prostate and coronary thrombosis.

Seth Marshall Fitchet * Boston; Harvard Medical School, Boston, 1921; fellow of the American College of Surgeons; served during the World War; served in various capacities on the staffs of the Children's Hospital, Massachusetts General Hospital, New England Baptist Hospital and the Massachusetts Eye and Ear Infirmary, Boston, and the Josiah B. Thomas Hospital, Peabody; aged 52; died, September 26.

Frederick Henry Gunn * East St. Louis, Ill.; St. Louis University School of Medicine, 1909; fellow of the American College of Surgeons; past president of St. Clair County Medical Society and the Southern Illinois Medical Society; member of the surgical staffs of St. Mary's and Christian hospitals; aged 56; died, September 26, in the Temple University Hospital, Philadelphia, of carcinoma of the liver.

John McCrea Dickson * Gettysburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; fellow of the American College of Surgeons; served during the World War; for many years chief of the surgical service of the Annie M. Warner Hospital; on the staff of the Chambersburg (Pa.) Hospital; aged 50; died, September 15, of cerebral hemorrhage.

Frank Blinn Dorsey Jr. * Keokuk, Iowa; State University of Iowa College of Medicine, Iowa City, 1912; past president of the American Association for the Study of Goiter; secretary of the Lee County Medical Society; on the staffs of the Graham Protestant Hospital and St. Joseph's Hospital; aged 50; died, September 1, of acute coronary occlusion.

Chris E. Emery, Butte, Mont.; Chicago College of Medicine and Surgery, 1917; member of the Medical Association of Montana; past president of the Silver Bow County Medical

Society; served during the World War; formerly county physician; in the staff of St. James Hospital; aged 45; died, September 21, in a hospital at Pasadena, Calif.

Ernest Leland Davis * Springfield, Mass.; Tufts College Medical School, Boston, 1906; member of the American Roentgen Ray Society and the New England Roentgen Ray Society; served during the World War; on the staffs of the Springfield Children's and the Shriners' Hospital for Crippled Children; aged 67; died, September 10.

David Ralph Bowen, St. Petersburg, Fla.; Jefferson Medical College of Philadelphia, 1894; member of the American Roentgen Ray Society; past president of the Philadelphia Roentgen Ray Society; aged 67; served at various times and in various capacities on the staff of the Pennsylvania Hospital, Philadelphia, where he died, September 6.

David Maxwell Marks * Jersey City, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1916; served during the World War; served in various capacities on the staffs of the Hudson County Hospital, Secaucus, and the Fairmount Hospital; aged 46; was shot and killed, September 15, by an unknown assailant.

Richard H. Whalen, Tama, Iowa; Illinois Medical College, Chicago, 1905; Hahnemann Medical College and Hospital, Chicago, 1905; member of the Iowa State Medical Society; formerly physician in the Indian Service; at one time county coroner and health officer; aged 65; died, September 4, of coronary thrombosis.

Loran Ernest Orr * Springfield, Ill.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1907; coordinating epidemiologist to the state department of health; at one time superintendent of Cass, Logan, Mason, Menard and Sangamon counties; aged 56; died, September 10, of coronary thrombosis.

George Stevenson * Mount Morris, N. Y.; Jefferson Medical College of Philadelphia, 1903; member of the Association for Research in Nervous and Mental Diseases; aged 77; died, September 11, at the Mount Morris Tuberculosis Hospital of pulmonary tuberculosis and diabetes mellitus.

Thomas Manning, New Rochelle, N. Y.; Bellevue Hospital Medical College, New York, 1890; member of the Medical Society of the State of New York; aged 75; on the staff of the New Rochelle Hospital, where he died, September 5, of chronic nephritis, myocarditis and arteriosclerosis.

Nellie Schenck, Long Beach, Calif.; Eclectic Medical Institute, Cincinnati, 1889; Southwestern Homeopathic Medical College and Hospital, Louisville, Ky., 1899; on the staffs of the Seaside Memorial and Community hospitals; aged 77; died, September 11, of cardiorenal disease.

Edgar Kirkland Dun Van, Chelsea, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1897; member of the Iowa State Medical Society; aged 67; died, September 24, in the Mercy Hospital, Cedar Rapids, of coronary sclerosis.

James Edward Francis Cogan * Cleveland; Jefferson Medical College of Philadelphia, 1896; fellow of the American College of Surgeons; visiting ophthalmologist to St. Alexis Hospital; aged 68; died, September 22, of aortic stenosis and coronary sclerosis.

Gustave Arthur Childgren * Burlington, Iowa; University of Minnesota College of Medicine and Surgery, Minneapolis, 1892; member of the American Psychiatric Association; aged 74; died, September 17, in the Mercy Hospital of acute cardiac dilatation.

George Augustine Marion, Rochester, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; served during the World War; aged 70; died, September 14, in the Highland Hospital of carcinoma of the pancreas with metastasis.

John William Mann, Washington, D. C.; University of Pennsylvania School of Medicine, Philadelphia, 1917; member of the Medical Society of the District of Columbia; served during the World War; aged 45; died, September 28, of coronary occlusion.

Robert Q. Rowse * Sioux City, Iowa; Medical College of Ohio, Cincinnati, 1893; fellow of the American College of Surgeons; attending surgeon to St. Joseph's Methodist and Lutheran hospitals; aged 69; died, September 27, of coronary occlusion.

George E. Ellis, Dunkirk, N. Y.; University of Buffalo School of Medicine, 1891; formerly health officer and school physician; at one time on the staff of the Brooks Memorial Hospital; aged 75; died, September 26, of arteriosclerosis.

James Wiley Thomason, Midway, Ala.; University of Alabama School of Medicine, 1910; member of the Medical Association of the State of Alabama; for many years member of the county school board; aged 59; died, September 12.

Herbert Piercy Nottage, Ontario, Calif.; Harvard Medical School, Boston, 1886; member of the California Medical Association; served during the World War; aged 75; died, September 15, in the San Antonio Community Hospital, Upland.

Saul Alfred Cloutier, Reno, Nev.; School of Medicine and Surgery of Montreal, Que., Canada, 1901; served with the Canadian Army during the World War; aged 63; died, September 10, of myocarditis and cerebral thrombosis.

Marcus Solomon Oliver, Chicago; Northwestern University Medical School, Chicago, 1912; member of the American Urological Association; aged 54; died, September 11, of coronary thrombosis and chronic myocarditis.

Robert Moses Nichols, Sheboygan Falls, Wis.; Hahnemann Medical College and Hospital, Chicago, 1887; served during the World War; formerly postmaster; aged 76; died, September 30, of aortic insufficiency.

David Archer, Oshawa, Ont., Canada; Victoria University Medical Department, Coburg, 1889; University of Toronto Faculty of Medicine, 1890; L.R.C.P., Edinburgh, and L.R.C.S., Edinburgh, 1890; died, September 20.

Glenn Russell Ford, Endicott, N. Y.; Syracuse University College of Medicine, 1919; on the staff of the Ideal Hospital; aged 46; died, September 9, of duodenal ulcer, bronchopneumonia, nephritis and myocarditis.

John Hiram Wilson, Keokuk, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1907; aged 56; died, September 26, in St. Joseph's Hospital of an accidental gunshot wound.

Charles Emonual Eugene Pannaci, Coral Gables, Fla.; Columbia University College of Physicians and Surgeons, New York, 1900; served during the World War; aged 61; died, September 1.

Henry Paul Rhode, Green Bay, Wis.; College of Physicians and Surgeons of Chicago, 1894; aged 66; died, September 28, in St. Vincent's Hospital of myocarditis and appendiceal abscess.

Moses E. Haase, Cedar Rapids, Iowa; St. Louis Medical College, 1882; member of the Missouri State Medical Association; aged 77; died, September 10, of carcinoma of the bladder.

Sydney Abraham Stein, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; aged 70; died, September 29, of heart disease.

James A. Sparks, Ashland, Ky.; Kentucky School of Medicine, Louisville, 1900; on the staff of the King's Daughters' Hospital; aged 63; died, September 27, of coronary occlusion.

John Abraham Hoffman, New Holland, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1901; aged 66; died, September 12, in the Lancaster (Pa.) General Hospital.

Henry O'Keefe, Grand Forks, N. D.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1882; aged 81; died, September 2, in St. Paul, Minn., of bronchopneumonia.

Clinton B. Staley, Enfield, Ill.; Barnes Medical College, St. Louis, 1898; served during the World War; aged 68; died, September 22, as the result of a fall from his front porch.

James Harvey Craft, Bramwell, W. Va.; University College of Medicine, Richmond, Va., 1905; aged 65; died, September 24, of cardiovascular renal disease and uremia.

Blanche Leonora Heiss Sanborn, San Francisco; Hahnemann Hospital College of San Francisco, 1899; aged 70; died, September 27, of cardiorenal disease and arteriosclerosis.

John Ray Beatty, Butte, Neb.; University of Nebraska College of Medicine, Omaha, 1899; aged 64; died, September 30, in a hospital at Lincoln of coronary embolism.

Mathias C. Schenecker, Webster, S. D.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1894; aged 80; died, September 4, of carcinoma of the liver.

Milton Augustus Hardin, Norphlet, Ark.; St. Louis College of Physicians and Surgeons, 1907; member of the Arkansas Medical Society; aged 61; died, September 4.

Edward Napoleon Bywater, Grants Pass, Ore.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1903; aged 62; died, September 11.

D. C. Walker, Decatur, Ala.; Birmingham Medical College, 1905; member of the Medical Association of the State of Alabama; aged 62; died, September 8.

William Franklin Holmes, Brockton, Mass.; University of Michigan Homeopathic Medical School, Ann Arbor, 1891; aged 66; died, September 22.

John Gunnell Talbot, Burkesville, Ky.; Hospital College of Medicine, Louisville, 1897; served during the World War; aged 67; died, September 30.

Frank Hughes, Boston; Tufts College Medical School, Boston, 1910; aged 66; died, September 13, at his summer home in North Weymouth.

Erwin Walter Markham, Great Barrington, Mass.; University of Vermont College of Medicine, Burlington, 1899; aged 64; died, September 10.

Hugh Buck Nunn, Ripley, Tenn.; Kentucky School of Medicine, Louisville, 1893; for many years postmaster; aged 67; died, September 6.

William J. Kavanaugh, Brooklyn; Baltimore University School of Medicine, 1901; served during the World War; aged 59; died, August 22.

Franklin M. Skaggs, Ardmore, Okla. (licensed in Oklahoma under the Act of 1908); Confederate veteran; aged 55; died, September 19.

HYPERSENSITIVITY TO PITUITARY

To the Editor:—A clinical note in THE JOURNAL October 14 by Dr. Walter McMann reports a case of hypersensitivity to solution of posterior pituitary. I would like to add a case of my own to the few that have been reported.

An octigravida aged 36 was seen by me in August 1934 for antepartum care. She made only this one antepartum call, at which time it was found that all previous labors had been normal and that all children were living and well. The present pregnancy had progressed without incident, and the estimated date of confinement was about September 7. On September 4 she was delivered of a normal male infant at 4:50 a. m. Following the second stage of labor she was given 1 cc. of solution of posterior pituitary intramuscularly,* which is my routine practice. On completion of the third stage she complained of generalized itching and moderate dyspnea. This became progressively worse, and she was given epinephrine for no other reason than that the picture appeared to be one of anaphylactic shock; I had no idea as to the etiology. The symptoms gradually cleared up and by noon she was quite well.

She became pregnant again in 1935 and on July 8, 1936, was delivered of a normal female infant. In view of her previous experience I gave her only 4 minims (0.25 cc.) of solution of posterior pituitary following completion of the second stage of labor. Her previous symptoms recurred, but in a mild form, and subsided promptly on administration of epinephrine.

Her tenth pregnancy began in 1939 and she was delivered of a normal female infant on October 14. She was given no solution of posterior pituitary at any time during or after labor, reliance being placed on Adair's ergonovine orally following completion of the third stage.

It might be noted, incidentally, that different brands of solution of posterior pituitary were used on the two occasions. The only physical disorders in this woman's history are obesity in 1936, at which time she weighed 248 pounds (112.5 Kg.) and at present cholecystitis with stones. The latter was proved by x-ray examination.

WAYNE C. RYDBURG, M.D., Brooten, Minn.

OXYGEN THERAPY

To the Editor:—The clinical lecture on oxygen therapy by Dr. M. A. Blankenhorn in the October 7 issue of THE JOURNAL is inadvertently and unfortunately misleading.

"Cyanosis is the main and only important indication for oxygen therapy in pneumonia." This opening sentence in the lecture does not take into account the fact that a grayish color to the face is generally indicative of the more severe types of anoxemia. Furthermore, in peripheral circulatory failure the capillaries of the skin are collapsed and a cyanotic hue may not be discerned in the presence of the most profound anoxia. In anemia there may be insufficient hemoglobin to provide a bluish color to the skin, although a marked decrease in oxygen saturation of the arterial blood may exist. Cyanosis may be considered a reliable indication for oxygen therapy in pneumonia only when it is present. There are other important indications for oxygen therapy, such as a pulse which is elevated out of proportion to the fever, dyspnea, restlessness and irrationality, abdominal distention, rapid shallow respiration; namely, the symptoms of anoxemia which are indicative of oxygen want and which Dr. Blankenhorn himself referred to as resembling the toxic effects of infection.

"Oxygen treatment may not be successful in relieving anoxemia for a number of reasons other than reasons of technic. It cannot succeed if too much lung is consolidated or obstructed by exudate. It cannot succeed if the circulation is failing or if there is toxic depression of the respiratory center by infection or drugs." These remarks do not take account of the fact that oxygen in physical solution in the blood is increased in proportion to the pressure or concentration of oxygen in the air breathed. Thus, at 50 to 60 per cent of oxygen concentration in the inspired air there is an increase of two and one-half to three times the normal physically dissolved oxygen. Furthermore, the hemoglobin even of a normal individual can be additionally saturated by 5 per cent. The summation of these two influences (not reckoning the additional oxygen which penetrates partially obstructed areas of the lung, which may be considerable) will increase the oxygen content in 100 cc. of blood by almost 2 cc. Since from 4 to 6 cc. of oxygen is consumed in 100 cc. of blood as it passes from artery to vein, an increase of 2 cc. has considerable physiologic significance. Reference to the oxygen dissociation curve indicates that a substantial elevation in oxygen tension takes place under these circumstances.

Oxygen treatment in the conditions referred to is frequently of great importance. Studies during the past decade have shown that a failing circulation, whether due to congestive disease, coronary thrombosis or peripheral circulatory failure, is especially aided by inhalation of oxygen enriched atmospheres (Barach, A. L., and Richards, D. W.: Effects of Treatment with Oxygen in Cardiac Failure, *Arch. Int. Med.* 48: 325 [Aug.] 1931. Levy, R. L., and Barach, A. L.: Therapeutic Use of Oxygen in Coronary Thrombosis, *THE JOURNAL*, May 3, 1930, p. 1363. Freeman, N. E.; Show, L. J., and Snyder, J. C.: The Peripheral Blood Flow in Surgical Shock, *J. Clin. Investigation* 15:651 [Nov.] 1936).

In toxic depression of the respiratory center by drugs oxygen treatment is also of value to prevent asphyxia, in some instances employed with carbon dioxide. The histotoxic anoxias, for example, produced by ingestion of alcohol, have been shown to be ameliorated by inhalation of oxygen (van Wulften, Palthe, P. M.: *Deutsch. Ztschr. f. Nervenhe.* 92:79, 1926. Barach, A. L.: The Action of Oxygen in Counteracting Alcoholic Intoxication, *Am. J. Physiol.* 107:610 [March] 1934. McFarland, R. A., and Barach, A. L.: The Relationship Between Alcoholic Intoxication and Oxygen Want, *Am. J. M. Sc.* 192:186 [Aug.] 1936).

It is my belief that oxygen tents should generally have 50 per cent oxygen rather than from 35 to 40 per cent, since these concentrations do not always raise the arterial oxygen saturation as near to the normal range as higher concentrations, and since the administration of very high concentrations of oxygen has been found valuable under certain conditions (Barach, A. L.: Methods and Results of Oxygen Treatment in Pneumonia, *Arch. Int. Med.* 37:186-211 [Feb.] 1926. Evans, J. H., and Durshodwe, C. J.: *Anesth. & Analgesia* 11:193 [Sept.-Oct.] 1932. Boothby, W. M.; Mayo, C. W., and Lovelace, W. R.: One Hundred per Cent Oxygen: Indications for Its Use and Methods of Its Administration, *THE JOURNAL*, August 5, p. 477. Fine, J.; Hermanson, D., and Frehling, S.: Further Clinical Experiences with Ninety-Five per Cent Oxygen for the Absorption of Air from the Body Tissues, *Ann. Surg.* 107:1-13 [Jan.] 1938). Oxygen may also be administered in conjunction with positive pressure, vaporized solutions of neosynephrin and epinephrine as well as with helium, but it is not my purpose to discuss the importance of oxygen therapy in pneumonia but rather to point out certain differences in emphasis or opinion in my views to those expressed in Dr. Blankenhorn's lecture.

ALVAN L. BARACH, M.D., New York.

POSTPARTAL CARE OF THE URINARY BLADDER

To the Editor:—At the annual session of the American Medical Association in 1939 TeLinde read a paper on the routine instillation of an ounce of a 1 per cent solution of mercurochrome into the bladder of gynecologic patients before they left the operating table. In this way he was able to reduce materially the incidence of postoperative catheterization. Since many patients have to be catheterized after delivery conducted under anesthesia, I determined to try TeLinde's plan in obstetrics. On my return from St. Louis I saw two patients being catheterized, one of whom developed a cystitis. I lost no time in putting the plan into operation. One hundred and fourteen obstetric patients, all delivered under an anesthetic, have been treated in this manner, and only two have been catheterized. One of these, I might say, had been in labor three days and had been dribbling urine for twenty-four hours before she was sent into the hospital. Her bladder was greatly distended. She complained more of the bladder pain than she did of the labor pains, and her physician had been giving her morphine to make it bearable. Had I been trying for a favorable record for the plan I should have omitted the instillation of mercurochrome into the bladder after delivering this patient. Nevertheless, it seems to be a simple and worthwhile addition to the delivery technic.

M. PIERCE RUCKER, M.D., Richmond, Va.

VERRUGA PERUANA

To the Editor:—In view of the editorial in *THE JOURNAL* July 15, page 235, in which reference is made to Dr. Trigo Arce having reported clinical cases of verruga peruana in the Yungas in 1935, it might be in order for one who has now spent nearly two years of continuous practice in the Yungas of Bolivia to give a little report on the possible presence here of this disease. I have not had an opportunity to communicate with Dr. Trigo Arce before making this report.

"Septique" or "tzerktiti" is one of those sneeze-cough-and-spit Aymara Indian words, and I would suggest that any one with false teeth trying to pronounce it for the first time do so in private. "Septique" or "tzerktiti" is used commonly by the Indians as the name for yaws or frambesia. Of course they do not always make exact diagnoses and at times may apply the term to cutaneous leishmaniasis or fungous cutaneous infections. This "tzerktiti" responds rapidly to neoarsphenamine, gives a positive Kahn reaction, does not usually produce a striking anemia unless associated with other disease, is not highly fatal and, if not treated, tends to run a chronic course of several years. The word "siete" I have heard less often and usually spoken of as "siete años" (seven years) and is applied to chronic sores that run a course of several years.

As I have stated before, I have practiced here almost two years now and I have not seen a case that I would suspect as being verruga peruana. My attention has been called to the disease, as several of our missionaries have contracted it in Peru and some have died. The Sanatorio y Hospital de Sud Yungas, of which I am at present medical director, has been in operation in Chulumani, the capital of the province of South Yungas, for about ten years. It draws its patients from both North and South Yungas as well as from the more outlying districts. Although I have gone over the records of the hospital for these ten years I have not found any cases even tentatively diagnosed as verruga peruana or Oroya fever. Our present head nurse, an American who has been here since 1934, states that she has not known of any cases here. The Peruvian pharmacist in town, José Keiffer, who has seen cases of the disease in the hospitals in Lima, Peru, and who has resided here since 1932, states that he has seen no cases here, nor has he heard of any. I have also asked several large property

owners who employ many peons, and they state that they have never heard of the disease.

Our climate, elevation and housing conditions compare favorably with other regions of the world where the disease is reported. We also have a large population of Peruvian Indians, but they come for the most part from the region about Lake Titicaca, where the disease is not generally known. In view of these facts it is possible that this illness might present itself here at some future date, but for the time being I believe it is one of the few diseases we have been fortunate in escaping here.

WALDO W. STILES, M.D., D.N.B.,
Chulumani, South Yungas, Bolivia.

VULVOVAGINITIS IN PREGNANCY

To the Editor:—We submit a few comments subsequent to those of Dr. H. Close Hesselstine with respect to our article "The Significance of Vulvovaginitis in Pregnancy" published in *THE JOURNAL* July 1, 1939, page 30.

All patients with symptoms and/or vaginal discharge had both the direct Sabouraud and the culture-transfer technic employed. The latter seemed to give a higher incidence of positive results and the incidence we reported was as we found it. Observations by one of us (E. G. W.) on 1,500 private patients shows a much lower clinical incidence.

The words "type of" should have preceded "lochia flow" in ascribing the postpartum disappearance of Monilia to the alteration in vaginal function. In our comment it is suggested that hyperestrinism with sequential vaginal changes in pregnancy may account for the appearance of Monilia in certain pregnant women. Inversely the rapid fall in estrogen results in glycogen-poor vaginal secretion during the time of lochia flow. Dr. Hesselstine is quite correct in criticizing the existence of any "lochia flow influence."

We are not of the opinion that oral thrush is necessarily a result of intrapartum infection from a mycotic vagina. We have encountered too many exceptions in this and other studies to believe it to be the rule.

The data reported are as they occurred in our study. There is no more finality in them than in other published data on the subject.

EDWARD G. WATERS, M.D.
EAKLE W. CARTWRIGHT, M.D.
Jersey City, N. J.

A SURGICAL PROCEDURE FOR ANGINA PECTORIS

To the Editor:—The report by Dr. Rupert B. Raney (*THE JOURNAL*, October 28, p. 1619) of a successful surgical procedure to relieve angina pectoris by cutting the efferent sympathetic fibers to the heart exclusive of the afferent fibers of the heart is confirmatory evidence of the experimental work which Mr. K. Jochim and I have recently reported (*Am. J. Physiol.* 126:395 [June] 1939) in which we demonstrated that the only coronary vasoconstrictor fibers present in the dog are adrenergic in character, tonically active and bundled in the sympathetic nerves. In our studies we did not find any cholinergic coronary vasoconstrictors in the vagi but only cholinergic vasodilators. It would appear, therefore, from the report of Dr. Raney that the innervation of the coronary arteries in man are similar to that reported by us in the dog. Hence, it is not necessary to assume, as the author did, that the sympathetic action of the coronary vessels is reversed in angina pectoris but rather that this is the innervation actually present in man. It would appear that, when angina pectoris results, the sympathetic coronary vasoconstriction may be exaggerated or, without exaggeration, that its effect is added to other constricting mechanisms, making it easier for severe coronary narrowing to occur.

LOUIS N. KATZ, M.D., Chicago

Queries and Minor Notes

QUERIES AND MINOR NOTES

1983

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ARRESTED TUBERCULOSIS

To the Editor:—What are the criteria for considering a case of pulmonary tuberculosis as arrested? I sought a position as medical officer in a government agency and was turned down because of pneumothorax. The reason was given that the condition of pneumothorax does not conform to the standards of an arrested state. Negative sputum for tubercle bacilli for three years under collapse therapy did not influence this ruling. I underwent pneumothorax. Exclusion of such persons from employment would therefore cause undue hardship to many who are apparently well. I should like particularly to know if the definition of the "arrested state" includes the pneumothorax condition.

M.D., New York.

ANSWER.—Pulmonary tuberculosis is usually considered arrested when the lesions are not causing constitutional symptoms and tubercle bacilli cannot be found in a concentrated specimen of sputum by microscopic examination, when the shadows on the x-ray film indicate that the lesions are stationary and there is no evidence of cavity formation. These conditions must be present over a period of six months, during the last two of which the patient has been taking exercise equivalent to two hours of walking daily. It should make no difference whether this so-called arrested state of the disease is brought about by the natural defense mechanism of the body alone, with or without strict bed rest, or by the aid of collapse therapy, such as artificial pneumothorax.

In some states, laws have been enacted which provide for the compensation of employees who fall ill from tuberculosis. Usually no provision is made whereby a person who has arrested or apparently cured pulmonary tuberculosis can sign a waiver for any subsequent illness from this disease. Most physicians now know that pulmonary tuberculosis frequently is a relapsing disease and that in many of our sanatoriums 25 per cent or more of the patients are there for at least the second time. While it is true that some persons control their tuberculosis so completely that it never reactivates, it is also true that many patients, no matter how well controlled their disease appears to be or what a good rating they have, will have one or more subsequent relapses. Such facts often make employers feel that it is not safe to employ persons who have had clinical pulmonary tuberculosis. Moreover, it is well known that certain complications may develop with artificial pneumothorax, particularly empyema, and whether it is due to mixed infection or to tubercle bacilli, the condition may result in a long period of illness and even require operation on the chest. While such complications do not develop in a high percentage of patients with artificial pneumothorax, yet there are enough of these to make the employer question the advisability of taking the risk.

True, five years is not an exceptionally long time for a patient to be treated by artificial pneumothorax. Indeed, Rist of the Laennec Hospital in Paris considers this the minimum time. However, the majority of his patients have moderately or far advanced disease when the treatment is instituted. In this country there are a good many patients who have been on pneumothorax ten and some twenty or more years. Usually, however, they are persons who had far advanced disease with large cavities when the treatment was begun, and they, as well as their physicians, are fearful of the condition which may exist if their lungs are allowed to reexpand; that is, cavities may not be permanently closed. They are thoroughly cognizant of the possibilities of complications like empyema, but they would rather take the risk of such complications than that of reactivated pulmonary tuberculosis with cavities and tubercle bacilli in the sputum. Usually when a person with artificial pneumothorax is entitled to the classification of "arrested" or "apparently cured" from the standpoint of absence from symptoms and from tubercle bacilli, good working capacity and the like over a sufficient length of time, the word "collapsed" is placed in parenthesis immediately after the terms indicating the classification. Most certainly the contention that the exclusion of persons who are able to work but who have artificial pneumothorax would cause hardship to many who are apparently well individuals is right. There are thousands of persons in the United States at the present moment whose disease is controlled by artificial pneumothorax so that it is no longer contagious and who are actually engaged in full time work; that is, they hold the same kind of position and perform their duties just as well as persons

sons who have never had pulmonary tuberculosis. As long as they are kept under close observation with reference to the contagiousness of their disease, to make certain that they do not become menaces to their associates and to make certain that new lesions do not appear in other parts of their bodies and jeopardize their future, there is no logical reason why they should not continue to work.

A patient who is given artificial pneumothorax treatment and has the area of disease under a good state of collapse usually is much safer from the standpoint of his associates and his own health than the person who has his disease brought under control by the defense mechanism of the body, aided only by a dietetic-hygienic regimen such as is practiced in a sanatorium or a hospital.

In some states tuberculosis is not rated as an occupational disease and therefore industrial commissions have no jurisdiction over it. When an employee blames an employer for the development of his disease, the case must be settled amicably or tried in civil court. Even in such states, many employers have become fearful of this disease because unjust claims have been made against them and even juries have rendered verdicts to their disadvantage. This has led to the requirement of many employers of adequate examination for tuberculosis of all employees before they are accepted for any kind of work. After all, this is the ideal procedure, for unsuspected tuberculosis will not be determined in this manner and the fraudulent employee will not be able later to force his employer to pay for something for which he is not responsible. At the same time the trustworthy person may suffer a hardship.

The problem encountered is serious. Numerous attempts are being made to rehabilitate persons with clinical pulmonary tuberculosis. It has been suggested that waivers be provided for tuberculosis in contracts of such organizations as the industrial and insurance companies, but this seems to involve legal technicalities which are difficult to solve. Certainly a movement is in order that would lead to a provision for employment of rehabilitated tuberculous patients with safety to them, their fellow employees and their employers, from the standpoint of their personal health, that of their associates and legal requirements.

FOOT POUNDS OF WORK OF HEART

To the Editor:—How much work in foot pounds will a normal heart of an average 150 pound (68 Kg.) man do in one hour when he is at complete rest, sitting, standing and doing heavy manual labor?

Fred T. Fox, M.D., Lawton, Okla.

ANSWER.—The calculation of the amount of work in foot pounds accomplished by a normal adult human heart in one hour is at best extremely crude. There are many factors that cannot be expressed adequately at the present time without extensive formulas and without more knowledge of various factors than are possessed at the present time, some of which it might be difficult to ascertain—such factors as the viscosity of the blood, the elasticity of the vessels, the velocity of the circulation, the effect of gravity and the duration of the cardiac cycle. However, a rough estimate may be made by taking three simple variables: the pulse rate, the blood pressure and the amount of blood expelled by the ventricles at each beat.

Assuming that at complete rest the left ventricle expels 60 cc., or 2 ounces, of blood per beat at a rate of 60 beats a minute (120 ounces, or 7½ pounds, a minute) at a mean arterial pressure of 100 mm. of mercury or 130 cm. of water, or 51 inches (4¼ feet) of blood, then the left ventricle accomplishes roughly 32 foot pounds a minute, which, multiplied by 60, is 1,920 foot pounds an hour. This, however, represents simply the work of the left ventricle. Meanwhile the right ventricle also is active, doing probably about half the work of the left. If then 960 foot pounds an hour for the right ventricle is added to the 1,920 foot pounds for the left, there is a total of 2,880 foot pounds for the two ventricles. It may be assumed that there is a little extra work carried out by the auricles too, which would give roughly about 3,000 foot pounds an hour for the heart muscle at rest.

At hard work the ventricle can put out probably at least 5 ounces per beat or two and one-half times as much as at complete rest. The pulse rate may be assumed to go up to about 100 instead of 60, and the blood pressure may increase 25 per cent. This would increase the amount of work accomplished five times, which would be equal for the whole heart to about 15,000 foot pounds an hour. The amount of work done when the man is sitting and standing would be close to the amount of work done with the man at complete rest. In fact, in the standing position, if carried out any length of time, there would be actually less work than at complete rest because of the effect of gravity in depleting the amount of blood coming

back to the heart and therefore the amount of work accomplished by the heart. It should be understood, however, that these figures are rough and that it would be impossible to calculate with great accuracy the amount of work done by the human heart.

MANDIBULAR NERVE AND REFLEX PAIN

To the Editor:—A man aged 29 has had a constant pain over the mastoid region for nearly two years. No precipitating cause can be elicited in the history or physical examination. He has had alcohol injections elsewhere followed by excision of second and third cervical nerve branches. I believe that the area is supplied by the great auricular and mastoid branch of the second small occipital nerves, and their excision should give relief. The patient complains of a reflex pain in the upper half of the entire face on that side. Any suggestions to throw light on the subject will be appreciated.

M.D., California.

ANSWER.—It is a popular misconception that the excision of the superficial sensory nerves in such a disorder will afford relief. There is, of course, some precipitating cause and it should be discovered. An old chronic sclerosing mastoid disease must be thought of and ruled out by x-ray and aural examinations. Arthritis of the temporomandibular joint must be thought of, for it could conceivably cause such a pain. Likewise, arthritic change around the foramina of exit of the second and third cervical nerves must be looked for. The mandibular nerve is notorious for the reflex pain which it may produce about the ear or in other parts of the area of supply of the trigeminal nerve; such pain may arise from a carious tooth, intra-oral chronic lesions or old low grade inflammatory foci some place in the trigeminal area. Fontaine and Leriche have suggested a role assumed by the upper cervical sympathetic nerves in just this type of pain, and their discussion should be referred to with the thought that treatment of the superior cervical sympathetic ganglion and the sympathetic nerves on the carotid artery with procaine hydrochloride might afford relief (Leriche, René: The Surgery of Pain, translated by Archibald Young, Baltimore, Williams & Wilkins Company, 1939).

CRACKING JOINTS

To the Editor:—A patient complains of a peculiar cracking noise in the different joints on motion. There is no evidence of arthritis, the history is clear, and laboratory data are negative. The only thing that might have a bearing on the symptoms is the fact that several years ago she had large infected tonsils; this condition was followed by cholera. No cardiac symptoms are present, nor is there evidence of joint involvement other than as stated.

D. F. Russell, M.D., Van Wert, Ohio.

ANSWER.—The condition of cracking or snapping joints is occasionally a source of much worry to sensitive persons. When this symptom is present alone, without pain, swelling or other evidence of arthritis, it is of no clinical significance. The cracking has been explained on several bases. Its pathogenesis is similar to that of the cracking that is made by children and occasionally by adults when the distal phalanx of a finger is suddenly pulled distally. The surfaces of interphalangeal joints which are suddenly pulled apart will cause a popping sound similar to, and perhaps produced in the same way as, the noise made by abruptly pulling the tongue away from the roof of the mouth. Just why this should occur more at certain times than at others in the same person or should be present to a high degree in some persons is not definitely known.

A roentgenogram, of course, should be taken to rule out the presence of loose bodies and a careful examination made to exclude other pathologic conditions. In the absence of these, however, the patient should simply be reassured that she has nothing to fear from this harmless symptom.

UNTOWARD EFFECTS FROM GONADOTROPIC SUBSTANCE

To the Editor:—Have there been any proved cases of premature epiphyseal closure when gonadotropic substance is given to the preadolescent child? Have any other permanent harmful effects been reported?

M.D., Nebraska.

ANSWER.—There is no published record of proved premature epiphyseal closure following the use of gonadotropic substance. Inquiry from several physicians who have made intensive studies in this field fails to reveal any knowledge of such premature osseous development. The possibility is recognized and has been the basis for caution in the use of large doses of gonadotropic substance before adult stature is achieved.

Other possible harmful aspects from the use of this factor would include the precocious production of adult size and activity of the male genitalia (Thompson, W. A., and Heckel, M. J.: Precocious Sex Development from an Anterior Pituitary-like Principle, THE JOURNAL, May 28, 1938, p. 1813).

TRICHOMONAS VAGINITIS IN YOUNG GIRL

To the Editor:—Please advise as to treatment of *Trichomonas vaginalis* vaginitis in a girl 7 years of age.

T. M. Watson, M.D., Greenville, N. C.

ANSWER.—If the child has no disturbing symptoms and only a slight discharge, all that is necessary is to keep the external genitalia clean by frequent washing with soap and water. If, however, there is true vaginitis, not only should soap and water be used liberally on the external genitalia but treatment must also be applied to the vagina. Since the vagina is small and the hymenal orifice tiny, no attempt should be made to cleanse the vagina except in refractory cases. A form of therapy which is simple and which can be carried out at home by the child's mother is the use of acidulated dextrose-lactose tablets as advocated by Karnaky, 0.3 Gm. (5 grains) each of boric acid, dextrose and lactose being sufficient material to make thirty tablets.

One of these tablets should be inserted into the child's vagina two or three times a day. This treatment is directed toward producing and maintaining an acid medium in the vagina. A medium in which *Trichomonas vaginalis* cannot survive. The tablets have a pH of about 3.

PALPATION OF ARTERY AND THROMBOSIS

To the Editor:—In palpating the brachial artery to determine its degree of sclerosis and tortuosity, one usually presses the walls of the vessel together. It has often occurred to me that some degree of trauma might be inflicted on the vessel by this maneuver, especially if it is superficial. Are there any reports of experimental or clinical studies to show whether intimal damage or even thrombosis can occur in this manner?

M.D., Tennessee.

ANSWER.—Trauma may cause a sclerotic plaque to project into the intima of an artery and thus cause thrombosis. However, as far as is known there is no report in which thrombosis has been produced by palpation of the brachial artery. Theoretically, thrombosis could follow such palpation in instances of atherosclerosis but actually the trauma is almost certainly too slight.

LEAD LINE IN BONES OF INFANTS FROM BISMUTH

To the Editor:—If a growing child with congenital syphilis is treated with bismuth compounds such as bismarsen, will the bones show a dense white line in x-ray films similar to a lead line at the growing ends of the bones? Will treatment with mercury produce such a line?

M.D., Massachusetts.

ANSWER.—The bones of infants treated with bismuth in the immediately neonatal period will show a bismuth line similar to that seen in the bones of the newborn of mothers who received treatment with bismuth during pregnancy. The effect is not seen in older children. The age at which it ceases to occur is not definitely known but probably is less than 1 year. Mercury causes no such effect.

SEAL RING CELLS AND FOURNIER'S SYNDROME

To the Editor:—In a case of scleroderma the presenter spoke about finding seal ring cells in the biopsy section. Will you kindly advise me what is meant by a seal ring cell? Also what is meant by Fournier's syndrome? I asked two syphilologists and got two diametrically different answers.

Albert S. Tenney, M.D., East Orange, N. J.

ANSWER.—The term "seal ring cell" has been used by Dr. Fred Weidman, of Philadelphia, to denote the atrophied fat cells which have assumed signet ring or seal ring shapes, as seen in scleroderma. In all probability "Fournier's syndrome" refers to the combination of interstitial keratitis and chronic painless swelling of the knee joints which sometimes occurs in late prenatal syphilis. It has been mentioned by Cole (Congenital and Prenatal Syphilis, THE JOURNAL, Aug. 21, 1937, p. 580).

TETANUS AND INSECT BITES

To the Editor:—In THE JOURNAL, September 2, page 964, appeared a question and answer on tetanus and insect bites or stings. This brings to mind a case of tetanus observed when I was a house officer at Massachusetts General Hospital. A man who was on the beach at Jamaica in the winter of 1931 had been bitten on the foot by sand fleas. He paid little attention to these bites, but when he was on the boat returning to Boston his jaws began to tighten and he was taken by stretcher to the hospital wards. I looked long and hard for the point of entry and finally discovered on area about the toe nail which measured 2 by 4 mm; this was excised by the surgeon, and cultures yielded tetanus bacilli. After massive doses of antitoxic serum the patient recovered. This is the only case of its kind that I have heard about or seen.

Earle M. Chapman, M.D., Eastern.

Texas June Report

NATIONAL BOARD OF MEDICAL EXAMINERS
SPECIAL BOARDS

Dr. T. J. Crowe, secretary, Texas State Board of Medical Examiners, reports the written examination held at Austin, June 19-21. The examination covered twelve subjects and included 120 questions. An average of 75 per cent was required to pass. Two hundred and six candidates were examined, 194 of whom passed and twelve failed. The following schools were represented:

Book Notices

Operative Orthopedics. By Willis C. Campbell, M.D. Cloth. Price, \$12.50. Pp. 1,154, with 845 illustrations. St. Louis: C. V. Mosby Company, 1939.

At last we have a book that lives up to its title. The volume is intended for the orthopedic specialist, the industrial surgeon and the general surgeon. It is written out of the experience of a small group who have had tremendous experience and excellent guidance by an administrator and capable technician. The book should be well received by orthopedic surgeons, industrial surgeons and general surgeons. The author has correlated the mechanical and surgical principles of orthopedic practice and has emphasized the practical physiologic principles. The choice of material is fine and the presentation, composition and organization of the book are excellent. The author has drawn freely from the literature, and his choice is most acceptable. Operations are described and grouped according to the diseases for which they are most applicable. The chapter on surgical technic includes preparation before and after treatment; there are also chapters on apparatus and surgical approaches.

Some of the features of the book deserving special mention are the sections on arthroplasty, stabilization, joints and the treatment of malunited and ununited fractures. There is an interesting diagrammatic presentation of calcium metabolism; also a handy table of blood and urine changes in bone diseases, including serum calcium and phosphorus and serum phosphatase. A long chapter covers apparatus, plaster casts, splints and skeletal traction. Another long chapter concerns low grade disorders of joints, including arthritis, backache, sciatica, facetectomy, section on the piriformis muscle and section on the iliotibial band. One of the especially good sections is that on arthroplasty, toward which the author has contributed so much classic work. He is one of the pioneers and one of the international authorities on this subject.

Traumatic lesions of the joints are discussed, including internal derangements of the knee, disturbances and injuries to ligaments around the knee and osteochondritis dissecans. Dislocations are described in detail. The section on fractures is excellent. The chapter on malunited fractures is probably one of the features of the book. To those who know the literature the wonderful contributions of the author on malunited fractures are excellent. The section on delayed union and nonunion of fractures is good, also the section on acute and low grade disorders of the bones, including osteomyelitis. Noteworthy too is the material on tumors of bones, joints and soft tissue, which cover well these aspects.

Favorable comment is due the composition, format and beautiful character of the majority of the illustrations. Special mention should go to Dr. Hugh Smith for his collaboration. The publishers may be congratulated for beautiful work with the marvelous material with which they dealt.

A Visual Motor Gestalt Test and Its Clinical Use. By Lauretta Bender, M.A., M.D., Senior Psychiatrist, Psychiatric Division, Bellevue Hospital, New York. Research Monographs No. 3, American Orthopsychiatric Association. Lawson G. Lowrey, M.D., editor. Cloth. Price, \$3.50. Pp. 176, with 75 illustrations. New York: American Orthopsychiatric Association, 1938.

This monograph brings together and expands Dr. Bender's previous publications on visual motor gestalt function. The author assumes a familiarity with the classic teachings of gestalt psychology, which are not reviewed in the book. She defines the gestalt function as "that function of the integrated organism whereby it responds to a given constellation of stimuli as a whole; the response itself being a constellation, or pattern, or gestalt." The material offered is based on studies of psychiatric patients, of normal adults and children by use of a series of patterns first devised by Max Wertheimer. Bender has selected nine of Wertheimer's original patterns and has studied the variations in capacity to copy these patterns dependent on differing levels of maturation or growth in the visual gestalt function and in organically or functionally determined pathologic states.

The first part of the book is devoted to theoretical considerations. In the second chapter the author observes the stages

of maturation the child passes through in achieving visual motor experiences enabling him to read and write and to perceive as does the adult. The responses of small children to the Wertheimer patterns and the spontaneous sidewalk drawings of children are here studied. In the child of 2 at first scribbling is a motor activity which may acquire some significance after production. By motor experiment patterns eventually are produced that may resemble the desired one. An enclosed loop "is the basis of all perceived form." The child tends to persevere in reproduction of any one learned pattern and initially to reproduce this whatever figure is offered as a stimulus. Between the ages of 4 and 7 there is rapid differentiation of form. The author traces the increasing accuracy in reproducing size and form and in motor control with advancing age. Movement and perception cannot be separated and "form in the perception of children . . . is the outgrowth of motion."

The author comments that the child's earliest play activities and spontaneous drawings constitute experiments in form and in spatial and temporal relationships. She concludes that the child gets satisfaction out of his new experiences which is complete enough for the given age of maturation; that there is a continuous reaching out for new experiments in which the child freely participates, so that a continuously expanding "gestaltung" is both experienced by and produced by the child.

The responses of low grade mentally defective persons to the visual patterns are utilized for the further study of development of visual motor patterns. The most primitive patterns are analyzed in detail. It is emphasized that some tendencies to reproduce the patterns are present at the three year level but that perceptual motor capacities which appear only at higher intellectual levels are functionally associated with some of the gestalt principles. Tendencies to revert to the more primitive patterns are always present.

A study of maturation in the primitive child is based on drawings obtained from native African children. Her drawings of designs from the army performance tests were utilized and were analyzed in accordance with the gestalt principles used by the author. Details of seven levels of accomplishment are described. The author concludes that the unschooled native children with no previous experience with paper and pencil copy the forms as well as do average American born and educated children. Spatial orientation must then be thought of in terms of the organization of the perceptual motor patterns, and the different maturation levels are alike in the "primitive" and the civilized child.

Movement and temporal factors are studied in the final two chapters of the theoretical part of the book. The factors that determine the gestalt are the stimulating pattern, the motility of the visual field which determines spatial relationships, the temporal factor, the motor reaction pattern of the individual and his attitudes toward the experience. These factors are inseparable but constitute "a total process which is the response of the whole organism to the total situation."

The second section of the book consists of eight chapters in which the visual motor gestalt function is studied clinically. Eight cases of organic brain disease in which sensory aphasia was conspicuous are reported. The studies show that "the gestalt response principles are never fixed but are the integrative response of the personality-as-a-whole in any given situation." The tendency to revert to more primitive patterns with brain injury and the orderly course of recovery of function in accordance with the laws of developmental maturation are demonstrated. Disturbances in the visual motor gestalt function in dementia paralytica, alcoholic psychosis and acute confusional states are reported; a chapter is devoted to schizophrenia and one to manic depressive psychosis. In the schizophrenics "the fundamental disturbance of splitting" is expressed by a dissociation in the gestalt figures. Fragmentation and perseveration of parts, micropsia, dissociation by spatial separation and bizarre responses were noted in the schizophrenic. Manic depressive patients, on the other hand, evidence much less disturbance of the gestalt function, their productions reflecting inhibition or compulsive meticulousness, at times florid embellishments in manic states.

Of particular interest is Dr. Bender's standardization of the gestalt function in a performance test for children. The responses of 800 nursery school and school children to the Wertheimer figures have been used for the standardization. The author regards the test as of value as a test of maturity of performance.

in visual motor gestalt function between the ages of 4 and 11 years. A summarizing chart is presented, useful in determining the maturation level of individuals whose mental age is not above 11 years.

Analysis of the performances of mentally defective persons leads to the conclusion that the multiple causes of mental defectiveness may be classified as simple retardation in maturation, specific disabilities in the field of language, "dissociative phenomena which distort the whole personality," impulse disturbance, perceptual disturbances and confusional disturbances. The author concludes with reports on the use of the test in the study of malingering, in the Ganser syndrome and in the study of psychoneurotic individuals.

This book will be useful to physicians who are interested in problems of development and growth. The test devised by Dr. Bender will doubtless prove of clinical value as a performance test yielding specific information relative to perceptual functioning otherwise not readily available. It should prove to be particularly useful in diagnostic studies of retarded children and those suspected of being retarded. Where disturbances are primarily in the field of emotional development, the test will be of limited usefulness.

Die Hämaturie und ihre Behandlung. Von Privatdozent Dr. Rudolf Chwalla. Die Urologie in Einzeldarstellungen. Herausgegeben von Professor Dr. H. Boeminghaus. Boards. Price, 4.20 marks. Pp. 64. Leipzig: Georg Thieme, 1939.

In this monograph the author considers hematuria thoroughly. He stresses the importance of hematuria as a symptom of some underlying pathologic condition and states that the presence of blood in the urine always calls for a cystoscopic examination; that hematuria may be due to general disease processes outside the genito-urinary tract, as well as due to disease in the genito-urinary tract. He emphasizes the importance of following a definite routine in each case, which should include (1) demonstration of the presence of blood in the urine, (2) localization of the origin of the blood, (3) the diagnosis of the pathologic condition that makes the hematuria, and (4) the treatment. As a rule the experienced physician can recognize gross hematuria with the naked eye; he may be able to recognize even the presence of small amounts of blood in the urine. When doubt exists, one must resort to the use of the microscope and chemical tests. Changes in the color of the urine may be mistaken by the patient for the presence of blood, and some of the factors responsible are discussed.

The author stresses the importance of obtaining a comprehensive history and discusses its value, and he also calls attention to some of the important facts that may be obtained from a careful history. This is illustrated with statements showing some of the general causes of hematuria. Next in order is a careful urologic history, and special emphasis is given to the value and the information obtained from such a history. During the physical examination of the patient with hematuria, especial attention should be paid to the nutritional state of the patient, the appearance of the mucous membrane, heart and lungs, and so on. The various bits of information obtained by a careful physical examination are mentioned and discussed from the possibility of how much information can be obtained that will aid in making a presumptive diagnosis before resorting to the various special methods of examination.

The special methods of examination are discussed in detail. Anterior and posterior urethroscopy, cystoscopy, chromocystoscopy, ureteral catheterization, x-ray examination and retrograde and intravenous pyelograms are presented. Much discussion is presented regarding the technique of these various procedures. Attention is called to the fact that a kidney which shows disturbance in function may not necessarily be the cause of the bleeding and that the bleeding may have its origin in latent and unrecognized disease in the opposite kidney.

The cause of the hematuria is presented under three headings: 1. Hematuria due to general disease processes. Among these he mentions hemorrhagic diathesis, the various forms of nephritis, acute infectious diseases and chemical intoxications. Although lesions of the renal vessels are rare, they may be the cause of profuse bleeding and one must consider them in the differential diagnosis; they include embolism and thrombosis of the renal artery, aneurysm, thrombosis and thrombophlebitis of the renal vein. 2. Hematuria due to primary lesions of the genito-urinary

system. The author stresses the frequency of malignant tumor as a cause of hematuria. As one would expect in a monograph of this kind, lesions of the urinary tract that make hematuria are given careful detailed discussion and are given a good deal of space. 3. Hematuria in infancy and childhood. Owing to the rarity of the condition, this phase of the subject receives short but detailed discussion.

The author discusses the treatment of hematuria under the following headings: general measures that are directed toward controlling or stopping the bleeding, various forms of local instrumental measures, and the appropriate measures to relieve the underlying pathologic condition which is causing the bleeding.

One is impressed by the long list of drugs recommended (many proprietary).

Getting Ready to be a Father. By Hazel Corbin, General Director, Maternity Center Association, New York, N. Y. Cloth. Price, \$1.25. Pp. 48, with illustrations. New York: Macmillan Company, 1939.

This book, by the general director of the Maternity Center Association in New York, is dedicated to the men who attended the first class for expectant fathers at the Maternity Center Association. It is written in narrative form, describing what happens to the fetus from month to month, the processes of labor and the attitude of the husband toward these processes. It describes the choice of a doctor and of a hospital and also tells what to do about grandmothers and grandfathers and diapers. It tells how to build a crib at home and how to fix up a nursery. There is even complete information to help the father in nursing the baby in every way except by supply of breast milk. There are also pictures which might as well have been omitted for all that they teach. Intelligent men do not need books of this kind except for a few hints which can be included in 300 words of text. The kind of men who need this book will never buy it. There is much to be said, however, for the holding of classes for expectant fathers where the right kind of teachers and lecturers are available.

Alcohol and Human Life Being Partly a Revision of "Alcohol and the Human Body," by the late Sir Victor Horsley and the late Dr. Mary Sturge and Others. By Courtenay C. Weeks, M.R.C.S., L.R.C.P. With foreword by Sir Thomas Barlow, F.R.C.P., M.D., F.R.S. Second edition. Cloth. Price, 6s. Pp. 455, with 20 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

The first edition of this book was published during 1928. The present edition is revised and enlarged. All profits from the book are to be devoted to educational work. The author says that alcoholic indulgence is still the greatest enemy Britain has to fear. His book is, of course, an argument for temperance and prohibition, preferably the latter. It provides massive data regarding the effects of alcohol on life, always with a tendency toward the worst that it does and with little to say about its values. A chapter called "Alcohol and the Duration of Life" is devoted to an analysis and dissection of the writings of Raymond Pearl on the same subject and comes to the conclusion that Pearl is wrong and has not established his case. The book is unfortunately not quite up to date, even in making the best possible use of material distinctly favorable to its point of view. In other words, it is an attempt at the use of scientific data for propaganda, which must inevitably result in something that is not quite scientific.

Hypertension and Nephritis. By Arthur M. Fishberg, M.D., Associate in Medicine, Mount Sinai Hospital, New York City. Fourth edition. Cloth. Price, \$7.50. Pp. 779, with 41 illustrations. Philadelphia: Lea & Febiger, 1939.

In its latest edition, this popular and authoritative textbook has been thoroughly revised. In previous editions the author managed to include all current information on the subject which was reliable, and this edition is no exception. Many important contributions have been made in the five years since the previous edition was published and the author has included most of them. The additions are fundamental contributions to the subjects and justify a new edition. The following are some of the important subjects which have been added: perirenal azotemia and the fundamental role of decreased blood flow in the pathogenesis; the mechanism and the pathogenesis of hypertension and its important complications; Goldblatt's important contribution; recent additions to our knowledge of kidney function tests, and the role of acacia and concentrated blood serum in the treatment

BOOK NOTICES

1988

of edema. In spite of the comprehensive presentation of experimental and scientific aspects of the subject, the author has not neglected the practical points in management. The practitioner will get just as much value from this book as those interested in the more scientific phases of the subject. This feature was always present in previous editions. The book justifiably enjoys a widespread popularity among students and practitioners as an authoritative source of practical and scientific information on nephritis and hypertension. The new edition perpetuates this reputation.

Manual of the Diseases of the Eye for Students and General Practitioners. By Charles H. May, M.D., Consulting Ophthalmologist to Bellevue, Mt. Sinai and French Hospitals, New York. Sixteenth edition, revised with the assistance of Charles A. Perera, M.D., Instructor in Ophthalmology, College of Physicians and Surgeons, Medical Department of Columbia University, New York. Cloth. Price, \$4. Pp. 515, with 387 illustrations. Baltimore: William Wood & Company, 1939.

That this comprehensive, thorough and interesting volume has passed through sixteen American editions with many reprintings, has been through eight British editions and has been issued in Spanish, French, Italian, Dutch, German, Japanese, Chinese and Portuguese, for the most part in more than one edition, would seem to leave little in the way of comment. The chapters concerning glaucoma, the lens, the retina, the optic nerve and errors of refraction have been rewritten. Additions in the text have been the inclusion of the visual standards for operating motor vehicles as approved by the Section on Ophthalmology of the American Medical Association. Six color plates have been added. Because of the practical and consistent scope of this work, the careful and meticulous adherence to sound fundamentals of the author and the characteristic reproductions of eye diseases, a critical reading fails to reveal many—if any—obvious errors. A few of the illustrations, because of the modern trend, might be replaced by those more familiar to the student of today. The usefulness of this well known textbook needs no comment.

The March of Medicine: Selected Addresses and Articles on Medical Topics 1913-1937. By Ray Lyman Wilbur, M.D., President of Stanford University, Stanford University, California. Cloth. Price, \$2.75. Pp. 280. Stanford University Press, 1938.

Here, under the print of the Stanford University Press, is a collection of selected addresses and articles on medical topics by Ray Lyman Wilbur, published between 1913 and 1937. Some of these articles appeared in medical periodicals; many of them, however, were delivered as casual addresses before lay organizations. Many of them are intimately associated with Dr. Wilbur's work in the medical field. The book provides also a bibliography of the writings of Dr. Wilbur from 1902 to the time of this publication. Many of the addresses concerned particularly with medical education reflect the position of the author as chairman of the Council on Medical Education and Hospitals of the American Medical Association. Readers will find in this book much of inspiration and stimulus, presented in a literary style that is distinctive and strong. The essays reveal the wide range of interests of the author and his leadership in American medicine.

Physiologie et pathologie du tissu osseux. Par René Leriche, professeur au Collège de France. Paper. Price, 100 francs. Pp. 459, with 65 illustrations. Paris: Masson & Cie, 1939.

The book covers the first annual lectures by the author as professor at the Collège de France. His fundamental idea is to show that bone is an important physiologic unit in the service of the "milieu intérieur" and not simply a mechanical support for the body. It constitutes a reserve interposed between the active calcium and the tissue calcium without which the body could not maintain its equilibrium. Thus in both health and disease affecting calcium metabolism the calcium of bones is in an incessant state of movement. This is true both in general and in local diseases of the skeleton as well as in injury and experiments affecting it. He discusses both the lysis and the deposition of calcium in disease processes in terms of general calcium metabolism. The work is of distinctly a philosophic character involving a great deal of theory as well as clinical and experimental observation and should be of the greatest interest to those interested in the fundamental aspects of the physiology and pathology of bone.

Recent Advances in Medical Science: A Study of Their Social and Economic Implications. By Sir Edward Mellanby, K.C.B., M.D., F.R.C.P., Secretary to the Medical Research Council. The Rede Lecture Delivered Before the University of Cambridge on 28 April 1939. Boards. Price, 75 cents. Pp. 62. Cambridge: University Press; New York: Macmillan Company, 1939.

This is the Rede Lecture, delivered before the University of Cambridge in April 1939, beautifully printed and bound for permanent literary collections. Brief mention of the trend of scientific advance is followed by a study of the effects of medical discovery on social life and also on hospital and other practice. Most significant is the chapter on medical knowledge as the limiting factor in public health schemes. Here the author says that the whole position of state action in health matters wants clarifying; sentiment and public appeal, associated with particular lines of action, ought to be eliminated, and each proposition ought to be considered only from the point of view of the results to be expected from administrative schemes in terms of saving lives and affording increased efficiency to individuals. Dr. Mellanby is convinced that medical science has almost "shot its bolt" as far as its beneficial effect on the population as a whole is concerned. He feels that the problems of the future are biologic in character, involving largely control of growth of population.

Claude Bernard, Physiologist. By J. M. D. Olmsted, Professor of Physiology, University of California. Cloth. Price, \$4. Pp. 272, with 11 illustrations. New York & London: Paul B. Hoeber, Inc. (Harper & Brothers), 1938.

To every student of physiology the name of Claude Bernard is as familiar as that of most of the presidents of our country. Especially welcome, therefore, is this appreciation of the great physiologist, written understandingly by one who is himself a physiologist and who is at the same time capable of evaluating Claude Bernard as a man. The only previous book-length biography of Claude Bernard in English was that of Sir Michael Foster. In preparing this book, the author consulted many original sources, including letters, and he is able to give a picture of the great physiologist better than any description heretofore available. The volume is inspirational and at the same time most instructive, because the fundamental contributions of Claude Bernard in every medical field are still a source of reference in the reports of modern research. The author has carefully evaluated the contributions of Bernard in each of the various fields, and he concludes with an estimate of the contribution of the great French physiologist to philosophy. The book is supplemented by an excellent bibliography and an index.

Ideal Weight: A Practical Handbook for Patients. By W. F. Christle, M.D. Cloth. Price, 5s. Pp. 111. London: William Heinemann, Ltd., 1938.

To the great number of books already available regarding reduction of weight for those who are obese, comes this volume from a British publisher. It contains the kind of data that many people require regarding caloric intake and the amounts of energy necessary to use up the calories. Few people realize that three lumps of sugar provide enough energy for a one mile walk and that you can play nine holes of golf on a medium size potato. The author provides brief discussions of the fundamental facts regarding food and includes a discussion of the various types of food, such as appetizers, cereals and beverages. He concludes with a table of foods and the amount of calories available from ordinary portions, giving no attention whatever to the proteins, carbohydrates, fats, mineral salts and vitamins, which obviously must be given the most careful consideration by those who want to diet healthfully. There are many better books available in America for less money.

A History of Women in Medicine from the Earliest Times to the Beginning of the Nineteenth Century. By Kate Campbell Hurd-Mead, M.D. Cloth. Price, \$6. Pp. 569, with 70 illustrations. Haddam, Conn.: Haddam Press, 1938.

The average man will not want to read as much about the history of women in medicine as is here provided; namely, some 500 pages. In her various chapters the author takes us from medical women in ancient times down through the middle ages and through the seventeenth and eighteenth centuries. The book is immense in its detail and must have required

many hours of research. She gives the story of early medical practitioners among women in the United States and even the stories of those two famous charlatans Mrs. Mapp and Jane Stevens. Through an excellent index the book enables any one interested in any aspect of the work of women in the field of medicine to find here the data that he will require. The author writes in a forthright manner without much embroidery, so that the book is not easy to read, but it is unquestionably the most complete and authentic work of its kind available. Obviously, it has been impossible for the author to tell the history of women in medicine without repeating much of the history of medicine itself. Thus the reader is enabled to trace the record of discovery and the manner in which women participated in the advancement of medical science.

The Evolution of Chronic Rheumatism with Treatment to Correspond: The Preventive Clinic as a First Line of Defence. By R. Fortescue Fox, M.D., F.R.C.P. Founded on a Lecture Delivered at Margate, at the Congress of The Royal Institute of Public Health and The Institute of Hygiene, May, 1937. Paper. Pp. 26, with 5 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

Here the etiology of rheumatism is discussed. The treatment advocated includes particularly the use of sulfur waters and the use of baths, but little is said about pathology.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Amputation of Leg Attributed to Negligent Treatment of Fracture; Effect of Covenant Not to Sue.—The plaintiff fractured his left leg and was sent to the Seaside Hospital in Long Beach, Calif. The treatment there administered was unsuccessful and the leg was later amputated. Thereafter the plaintiff sued the two physicians who attended him, the hospital and the superintendent of nurses of the hospital, contending that the physicians were negligent in using too tight a cast and that the other defendants were negligent in not promptly advising the physicians of the discovery of this fact.

During the course of the trial, a claim superintendent for the insurance company representing the hospital and the nurse reached an agreement with the counsel for the plaintiff whereby for a consideration of \$6,000 the plaintiff executed a covenant not to sue the defendants represented by the insurance company. Thereafter the trial proceeded against the two physicians until on their motion the trial court directed a verdict for them. From the resulting judgment, the plaintiff appealed to the district court of appeals, second district, division 2, California, which affirmed the judgment of the trial court. The plaintiff then appealed to the Supreme Court of California.

There was competent evidence, said the Supreme Court, to necessitate a submission of the case to the jury. The fracture was reduced and the cast applied about 10 a. m. Sunday, August 9. One of the defendant physicians visited the plaintiff at 11:30 that same morning. He did not see him again nor communicate with him in any way until 8 p. m. When the physician left the plaintiff on Sunday morning he gave instructions to the nurses as to what they should do in an emergency resulting from a tight cast. Meanwhile, in the afternoon, the patient felt such severe pain that narcotics were administered, and his toes appeared swollen and a dark blue. The physician partially split the cast Sunday night, but the plaintiff continued to suffer great pain, and the swelling and discoloration continued. The condition of the plaintiff's leg became increasingly worse and required continual treatment until the amputation became necessary. A properly qualified medical witness for the plaintiff testified in response to a hypothetical question that the care of the plaintiff following the original treatment was not up to the standard of care and skill in the locality. He specifically criticized the failure to have constant after-care and observation of the leg when the

rigid cast was applied and testified that provision should have been made to notify the physician of the changes in condition which would have made it possible to open the cast much earlier. This expert testimony, the court commented, was enough to make a prima facie case, and the cross examination and conflicting views of the witnesses for the defendants raised only questions of credibility for the jury.

Two other medical witnesses called by the plaintiff corroborated the expert testimony previously given that the cause of the injury was a cast that was too tight. These physicians were asked hypothetical questions as to whether the conduct of the defendant physicians constituted due care, and an offer of proof was made to the effect that they would testify that it did not. The trial court, however, sustained objections to the questions on the ground that the witnesses were current practicing in Los Angeles and could not testify as to the standard of care in Long Beach, in which community the present case arose. The Supreme Court, however, could see no justification for such a narrow view. The cities of Long Beach and Los Angeles, the court pointed out, are in the same county; they are contiguous communities, both metropolitan in character, and their business centers are only about five miles apart. There is reason in the general requirement that the medical expert must be familiar with the standard of care in the particular locality in order that the standards of widely separate localities with different practices may be excluded. But to make the exclusion rest arbitrarily on a geographical line separating two cities of the same county with almost identical kinds of medical service would, in the opinion of the court, be a misuse of the rules of evidence and an unjustified emphasis on empty technicalities. Common knowledge, as well as the testimony of the physicians on both sides, convinced the court that the method used in treating the particular kind of fracture involved in this case was one in use throughout the world. And there was testimony to the effect that long prior practice in Los Angeles County, including Long Beach, showed that there was no difference in the treatment in the two communities. Both on principle and under the authority of the court was satisfied that the exclusion of the proffered testimony was error.

An expert witness for the defendants testified that the patient's leg was suspended in a "Böhler fracture frame" and that the witness had studied under Dr. Böhler and used his textbook and that his, the witness's, opinion was in part based on the book. The plaintiff's counsel then sought to cross-examine the witness by use of Dr. Böhler's book, and the trial court sustained objection to the impeaching question. This was improper, the Supreme Court said, for the rule against admission of such works as direct evidence is subject to the qualification that textbooks relied on by an expert witness may be used as a foundation for impeaching cross-examination.

The defendant physicians contended that the original for the defendants were sued as joint tort-feasors, or wrong-doers, and that the agreement resulting in the dismissal of the case against the hospital and nurse destroyed the plaintiff's cause of action against the other two defendants. They undertook to uphold the trial court's decision on the theory that the agreement constituted a release. But, said the Supreme Court, the agreement was entitled "Covenant Not to Sue and Covenant Not to Sue Further." It recited that the named defendants desired "an agreement and covenant not to sue and a covenant not to sue them or either of them further" or prosecute "any suit or suits now pending against them." It stated that the plaintiff "promises and agrees that he will not sue and/or sue further" the said defendants and that he covenanted and agreed to hold them harmless from any liability arising out of the accident or treatment. It concluded with the statement that the plaintiff did not waive any claims against the other defendants. This instrument, the court said, was unmistakably intended to constitute a covenant not to sue. Unlike a release, a covenant not to sue one joint tort-feasor does not relieve the others.

The judgment of the trial court directing a verdict for the defendants was therefore reversed.—*Lewis v. Johnson* (Calif. 80 P. (2d) 90; 86 P. (2d) 99.

Accident Insurance: Death of Donor During Blood Transfusion as Accidental Death.—The beneficiary obtained a judgment in the United States district court for the Eastern District of Virginia on a life insurance policy which provided double indemnity benefits if the insured died by reason of bodily injuries effected exclusively and wholly by external, violent and accidental means. The insurer appealed to the United States circuit court of appeals, fourth circuit.

A child of the insured was a patient in a hospital and was in need of a blood transfusion. The insured, then 34 years of age, finding that his blood was suitable, submitted himself for the purpose. He went to the hospital and walked up three flights of stairs to the operating room. The physician took his blood pressure, examined his heart and found him to be normal. The physician washed the insured's arm with antiseptic, applied a tourniquet and injected a needle into a vein, whereupon, before a tablespoon of blood had been withdrawn, the insured died. The undisputed evidence was that the insured was in good health at the time, that the operation was performed according to the customary and approved routine, that every act of the physician and of the insured was voluntary and intentional and that nothing unforeseen, unusual or accidental occurred in the manner in which the operation was performed. In short, although the death was a totally unexpected result, the acts which preceded it were done with due care and with specific intent. The physician who undertook to perform the transfusion operation, according to the appellate court, was of the opinion that "the death was caused by shock although he was not certain that it was not caused by heart failure."

The law of Virginia as declared by its legislature or by its highest court is decisive in this case, said the federal court. In *Ocean Accident & Guarantee Corp. v. Glover*, 165 Va. 283, 182 S. E. 221, the insured died from septicemia caused by an infection carried into the blood stream when he picked a pimple or boil inside his nose with a knife or needle. The Supreme Court of Appeals of Virginia in that case held that the death of the insured was effected by accidental means within the coverage clause of the policy involved. The decision was based on the idea that the word "accidental" in the policy was used in the ordinary and popular sense as meaning "happening by chance or not according to the usual course of things"; and since septicemia was not the probable consequence of the insured's act, recovery under the policy was justified. In the present case, the insurer contended that the only unexpected and unlooked for circumstance was the result, that is, the sudden death of the insured, whereas in the *Glover* case the means whereby the injury and death of the insured was produced may be fairly regarded as accidental because death followed the totally unintended and unexpected introduction of a germ into the body of the insured. To the circuit court of appeals, however, the distinction was not a valid one, because the insured in the *Glover* case voluntarily exposed himself to the risk of infection involved in picking the boil with a sharp instrument.

The circuit court of appeals, therefore, on the strength of the *Glover* case, agreed with the district court that the insured's death in this case was caused by bodily injuries effected exclusively and wholly by external, violent and accidental means within the meaning of the insurance policy, and the judgment for the beneficiary was affirmed.—*American Nat. Ins. Co. of Galveston, Tex., v. Belch*, 100 F. (2d) 48.

Malpractice: Negligence in Diagnosis of Hip Fracture.—The appellee injured his right hip and the appellant physician, after making a roentgen examination, diagnosed the injury as an impacted complete fracture of the surgical neck of the femur and treated it as such. The patient, however, continued for several years to have trouble with the hip and finally consulted another physician, who discovered that the shaft had slipped past the head of the femur for a distance of about 2 inches, resulting in only a fibrous union. The patient then brought suit and obtained a judgment in the United States district court, District of Idaho, eastern division, against the physician who had first treated him, the appellant in this case, the judgment being based principally on the finding that the physician diagnosed and treated the injury as an impacted fracture when the fracture was unimpacted. This judgment was reversed by the United States circuit court of appeals, ninth

circuit, because in the opinion of the court there was not sufficient evidence to warrant a submission to the jury of the question of whether or not the physician was negligent in making the diagnosis of impacted fracture.—*Moore v. Tremelling*, 78 F. (2d) 821; abstr. J. A. M. A. 106:1685 (May 9) 1936.

The case was tried a second time, the patient again obtained a judgment and the physician again appealed to the United States circuit court of appeals, ninth circuit.

The evidence was conflicting, said the court of appeals, as to whether or not there was negligence in the diagnosis and treatment of the fracture, but there was ample evidence on which to submit that question to the jury. There was testimony by the patient, his son and son-in-law, who were present at the time of the examination of the patient by the physician, and testimony by the patient's daughter that his right foot everted, or rolled over. On the other hand, the physician testified that the foot did not evert or roll over but agreed with all the other experts that if the foot did in fact evert the diagnosis should have been that the fracture was unimpacted. There was testimony that according to the standard of medical practice at Paris, Idaho, several roentgenograms should have been taken at once at different angles to determine the nature of the fracture and that other roentgenograms should have been taken later, one when the plaster cast was applied and another when it was removed. The physician took only one roentgenogram at the time of his diagnosis and none later. Expert evidence was given that the amount of pain, of mobility and of crepitus, if any, should have indicated to a practitioner of ordinary skill whether or not the fracture was impacted. Another expert witness testified that from his examination of the roentgenogram taken by the appellant if the foot was rolled over or everted the fracture was an unimpacted one. A roentgenologist testified that in his opinion from an examination of the roentgenogram taken by the appellant the fracture was unimpacted. A physician who practiced in a locality similar to Paris, Idaho, testified that from examination of a roentgenogram taken under his supervision some two years after the injury the fracture appeared to have been unimpacted. He testified that the recognized practice in diagnosing an unimpacted fracture was to take several roentgenograms, sometimes as many as three or four views, and that it was necessary to use a great deal of care in the manipulation of any injured hip, "until you have had your pictures and know just what has happened." With reference to evidence tending to show that the result would have been better had there been no negligence in treatment or diagnosis, the court said there was definite testimony by expert witnesses which justified the submission of the question to the jury.

After reviewing the entire record, the court of appeals could find no prejudicial error in it and the judgment in favor of the patient was affirmed.—*Moore v. Tremelling*, 100 F. (2d) 39.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Ascorbic Acid Requirement in Rheumatoid Arthritis.—Hall and his associates determined the ascorbic acid content of the blood of fifty-six patients with rheumatoid arthritis as compared with twelve normal individuals on a similar dietary regimen. Of the fifty-six patients fourteen showed an ascorbic acid level in the plasma of 0.8 mg. or higher per hundred cubic centimeters, which is within the accepted normal range. Nine had values between 0.5 and 0.8, whereas thirty-three had levels below 0.5 mg. Five of the patients who had plasma levels above 0.8 mg. had supplemented the hospital diet at the time of the survey with sufficient citrus fruits or orange juice to account for an additional daily intake of 80 mg. of ascorbic acid. Ten of the twelve normal subjects had levels of ascorbic acid in the blood plasma ranging between 0.9 and 2 mg. per hundred cubic centimeters and two had values of 0.6 and 0.25 mg. respectively. The patient with the lowest level of ascorbic acid stated that he rarely ate fruits or uncooked vegetables included in the diet. Studies on the requirements of an arthritic individual for ascorbic acid showed that this was between 100 and 200 mg. daily or between two and four times that required by a normal person. None of the arthritic patients showed symptoms associated with scurvy itself in spite of the fact that many had ascorbic acid levels below that usually present in scurvy. After eight months, during which time the patients were given ascorbic acid daily and their blood was known to be saturated with the vitamin, no clinical improvement which could be attributed to the ingestion of the acid was observed. Some patients improved during this period but others continued unchanged or became worse as judged by the condition of their joints, hemoglobin or failure to gain weight and slowing of the erythrocyte sedimentation rate. No increase in the erythrocyte count was found in any of the patients, although occasionally sporadic but slight increases in the reticulocytes were observed. The study indicates that the ordinary hospital diet was inadequate in its ascorbic acid content to supply the increased demands of the rheumatoid arthritic patient and may lead to a general revision of diets in institutions devoted to the care of this disease.

Sulfapyridine for Pneumococcal Pneumonia.—From July 1, 1938, until June 20, 1939, Long and Wood state that 139 adult patients were treated in the Johns Hopkins Hospital for presumptive pneumococcal pneumonia. Pneumococci, identi-

fied by specific antisera, were obtained from the sputums of 124 of these patients and pneumococci were identified in the sputum of five, but it was not possible to type the organisms and from ten patients pneumococci were not isolated at any time during the course of their illness. The fatality rate in the 139 cases was 7.2 per cent. This low death rate is attributed by the authors to the use of antipneumococcus serum, sulfapyridine and serum and sulfapyridine. Sulfapyridine is irregularly absorbed from the gastrointestinal tract of human beings. A relatively large fraction of the sulfapyridine absorbed may be conjugated to acetylsulfapyridine. The soluble sodium salt of sulfapyridine which may be given by the intravenous route is a valuable adjunct in the treatment of severe pneumococcal infections. If relapses of pneumonia are to be avoided, sulfapyridine must be continued until convalescence is established. Renal calculi, composed of acetylsulfapyridine, may form in the urinary tracts of patients who are receiving sulfapyridine. The abandonment of type specific serum in the treatment of pneumonia is not indicated in the light of the authors' experience.

Hearing Acuity and Stammering.—Harms and Malone point out that speech defects in pupils of elementary grades have been estimated by different investigators to be from 4 to 18 per cent, which percentage would mean that at least a million children have defective speech. Thus they outnumber the crippled, blind and deaf combined. It is estimated that 10 per cent of those with defective speech are stammerers. Speech is a social habit developed through imitation. This involves not only the mental motor mechanism but also the proper receiving mechanism. Therefore defective hearing is a legitimate cause for defective speech, especially if this defective hearing occurs during the ages when speech habits are being formed. As stammering is a type of speech defect, whatever principles apply to speech correction apply to stammering correction. In addition, the stammerer has some individual problems. The literature reveals no investigations to relate hearing acuity to stammering, although there is frequent reference made to the relation of the hearing acuity and certain types of speech defects. The greatest toll in hearing loss is taken by childhood diseases which occur during the first seven to eight years of life. The greatest good can be accomplished during these years. It is the authors' opinion that the hearing acuity of all school children should be tested by the end of their first year at school and that these tests are just as important as visual acuity tests. This testing should be done with audiometers, as investigators have found that examinations carried out by parents, school teachers and nurses miss the majority of these hard-of-hearing children. A national survey of all the schools for the deaf and hard of hearing have shown the authors that stammering is rare in those with a total loss of hearing. It becomes more frequent in those

with approximately 50 per cent loss of hearing. In sixty-two consecutive cases of stammerers who were unaware of any hearing loss there was a loss of from 10 to 22 per cent, which strongly suggests a relation between hearing loss and the development of stammering. Cases are cited of former normal hearing and speech in which subsequent disease resulted in poor hearing and was followed by stammering. Also a case is presented showing stammering on words falling within the island defect of hearing acuity. Hearing aids should be used for speech correction in these cases if the hearing cannot be improved to a useful level.

Capillary Structure in Schizophrenia.—The character of the cutaneous capillary structure of 1,100 schizophrenic persons was studied by Olkon and compared with that of normal persons. In cases of schizophrenia the cutaneous capillaries showed striking deviations, consisting of reduction in number, few comma shapes, a paler color, lack of uniformity in size and a variety of bizarre shapes—spiral, crescent, hairpin-like and stellate forms and dilated, amoeboid forms with pseudopodia. Moreover, the flow through the capillaries was seldom uniform; at times it was more rapid and at times slower than normal; at other times the contractions and dilatations were remarkably irregular. Another striking feature was the frequent occurrence of capillary hemorrhage among excited schizophrenic patients. In cases of hebephrenia of long standing, sparseness of capillaries was the most marked feature aside from the bizarre shapes already mentioned. Schizophrenic patients showed these changes, whereas normal persons of similar age did not. From the observations it is clear that in organic and vegetative derangements there are definite disturbances in the capillaries which may be corroborative evidence for the increasingly accepted theory that schizophrenia is a vegetative and metabolic disorder.

Brilliant Vital Red in Epilepsy.—Aird states that of six patients suffering from severe and varied forms of epilepsy, chosen because they had failed to respond to any accepted type of treatment, five, after intravenous injection of brilliant vital red, showed from slight to marked improvement in the frequency of the attacks, and the attacks of all six were reduced in duration and severity. The improvement lasted from four to seven months. Thus, as in the experimental work, the observations of Cobb and his co-workers were confirmed, an abstract of whose article appears in *THE JOURNAL*, Feb. 4, 1939, page 472. The author's conclusions are that the endothelium concerned with the formation of cerebrospinal fluid forms an effective protective barrier to the central nervous system. In animals with experimental epilepsy, brilliant vital red renders this "barrier" relatively impermeable to the passage of cocaine hydrochloride. The same effect presumably holds for the other convulsive agents (picrotoxin, strychnine, camphor and triphenylphosphite) tested in connection with brilliant vital red. As brilliant vital red affords protection in cases of human epilepsy, this fact affords strong evidence in support of the hypothesis that "convulsive toxins" and the endothelium of the hemato-encephalic barrier are factors of etiologic importance in human epilepsy and that the relation between them is analogous to that demonstrated in experimental epilepsy.

Sulfanilamide for Gonorrheal Ophthalmia.—Barbour and Towsley compare the results obtained in fifteen cases of gonorrheal ophthalmia treated with sulfanilamide with those obtained among fifteen similar patients treated before the drug was used at the University Hospital. In only one of the fifteen cases in which sulfanilamide was used did corneal ulcers develop after treatment with it was started. These remained superficial and healed rapidly with only tiny residual nebulas. Since of the fifty-five cases summarized from the literature there were none in which significant visual loss occurred after the administration of sulfanilamide was started, this makes a total of seventy cases in which serious corneal complications did not occur. Corneal ulcers developed in five of the fifteen cases in the control group after treatment was started. In two of these control cases (both in infants) useful vision was lost in both eyes. Since each corneal ulcer indicates a potentially blind eye, the decreased incidence of this complication with sulfanilamide therapy is an important economic and sociologic factor. The clinical improvement noted after the administration of sulfanilamide was started was frequently dramatic in its rapidity. No recurrence of discharge was noted in the group of cases in which sulfanilamide was used. Of the fifty-five cases reviewed, inconsequential recurrence of discharge occurred in only one of those in which treatment was adequate. In two cases the drug was temporarily discontinued in one because of toxicity, causing a hemolytic anemia (Willis); in both there was a moderately severe recurrence of discharge. The hemolytic anemia readily responded to transfusion, and the drug was again given with satisfactory results. Smears once negative remained negative in the authors' series and in those which they review from the literature. In no case in either group was there a persistent positive smear after the discharge had ceased. In one of the control cases positive smears were obtained fifteen days after the discharge had ceased. Mayou pointed out that virulent gonococci have been found twenty-eight days after all discharge had stopped. This point is significant from the standpoint of cross infection and reinfection. The average duration of the disease in the control group after treatment was begun was almost four times as long as in the group in which sulfanilamide was used. It took approximately four times as long for the discharge to become minimal in the control group. This means a substantial saving in the cost of hospitalization.

Dark Adaptation, Night Blindness and Glaucoma.—Feldman attempted to determine the causes, if any, of idiopathic night blindness, i. e. night blindness without any known accountable constitutional disease, and what relation, if any, there is between pathologic dark adaptation and night blindness. As glaucoma in the majority of cases is associated with pathologic dark adaptation, an attempt was made to correlate the frequency of night blindness in this condition. The study calls attention to the presence, but the none too frequent association, of night blindness in patients suffering with renal calculi and glandular and hepatic diseases. Night blindness is, however, frequently encountered in association with dietary indiscretions in which there is a definite lack of vitamin A in the food. In these cases the cure is effected in a reasonable period. However, even in

these cases the treatment may sometimes have to be prolonged before night blindness is overcome. Night blindness does not bear any relation to the intensity of pathologic dark adaptation. Thus, for example, many patients with hepatic disease whose dark adaptation curve almost approaches that of persons with pigmented retinitis do not necessarily have night blindness. It is important to determine whether the supposed night blindness from which a person suffers is not presbyopia instead. A high cholesterol content of the blood was observed in eight of the fourteen cases of glaucoma studied. Only with the examination of a large number of persons with beginning uncomplicated glaucoma who have not been operated on can it be determined whether or not defective sterol metabolism plays any part in the cause or the effect of the disease. It is possible that pathologic dark adaptation may be found of value as an indication in evaluating a phase of faulty metabolism of the liver.

Schizophrenoid Psychosis Following Head Injuries.—Shapiro found that of 2,000 cases of dementia praecox twenty-one showed a relationship between trauma and the onset of psychotic symptoms. In ten cases there was no evidence of brain injury, but the mental symptoms developed in such a close time relationship to a severe head trauma that the sequence of events cannot be disregarded. The patients were all of introverted personalities and had marked hereditary tainting, so that the possibility of schizophrenic-like reaction was present. As a result of the injury, this latent tendency became overt and the psychosis which followed the trauma was that of a so-called schizophrenia. The author concludes that in this group the trauma acted simply as a precipitating factor. In the other eleven cases evidence of brain damage was present. Confusion, dizziness, defects in memory and orientation, as well as persistent headaches with irritability do not belong commonly in a schizophrenic-like picture. Furthermore, in seven of these cases the prepsychotic personality was well integrated and hereditary tainting was present in only two. The neurologic changes, the mixture of organic-like mental symptoms and the absence of any predisposing factors in the history suggest that in these cases the trauma did more than precipitate a psychotic reaction. In producing pathologic changes in the brain, the injury would seem to have contributed to the formation of the clinical picture. Although postmortem studies are as yet not available in this group, the development of a parkinsonian-like syndrome in one case and evidence of hemiplegia and convulsions in another suggests localized cerebral damage. In evaluating the part that trauma plays in the schizophrenic-like picture, the personality as a whole should be considered. In all cases of so-called schizophrenia one should consider whether the psychosis is not attributable to some definite etiologic factor, such as trauma, infection or tumor. The need is in the exact evaluation of all mental symptoms, so that these patients (trauma) may be differentiated from the so-called schizophrenia in which no traceable etiologic factor occurs.

House Dust Antigen.—The Cohens and Hawver find that a dialyzed extract from a suitable sample of linters will give nonspecific reactions in normal and in allergic individuals when judged by the results of passive transfer experiments as well as by direct endermal tests. However, a one plus or larger endermal reaction with a 1:50 dilution of such an extract will be present in more than 90 per cent of individuals clinically sensitive to dust, and consistently negative controls are obtained in normal persons and in allergic persons not sensitive to dust. Guinea pigs can be sensitized and shocked with this linters extract. The active principle in this extract cannot be cottonseed or any of the contaminants ordinarily present in house dust extracts prepared from dust obtained from vacuum cleaners.

Effects on Lungs of Cement Dusts.—Gardner and his associates made an engineering survey of environmental conditions in a representative group of cement plants in various sections of the United States. The purpose of the survey was to determine the quantity and nature of the dust in the air and its effect on the lungs of the employees. Technical obstacles prevented exact determination of the proportion of atmospheric silica present in the air in the earlier phases of manufacturing; nevertheless much of the silica was too coarse to create danger. Modern preventive measures as well as intermittent exposures

in some of the departments likewise decreased exposure. Finished cement dust was found present in relatively high concentrations in the finishing mills and packing departments but this dust was practically devoid of free silica. Complete physical and x-ray examinations were made on 2,278 employees of eleven plants, 1,979 of whom worked in departments where they were exposed to dust of various kinds. The majority were white American men of slightly greater age distribution than in most industries. More than 55 per cent of the exposed employees had worked in the cement industry for more than ten years and 32 per cent for more than fifteen. Eighteen employees had worked for more than forty-five years. Since so many of them worked in several departments, an exact correlation between exposure to the dusts of different compositions and the pulmonary conditions was not possible. Analysis disclosed that prolonged inhalation of finished cement dust produced such slight anatomic reactions that practically no abnormality was seen in the roentgenograms. The mixed dusts of the raw mills were probably responsible for a limited number of well marked linear exaggerations, nondisabling in character. Only eight of the examined employees showed evidence of nodular fibrosis attributable to dust. In six of these cases exposure to silica dust in previous employment was probably responsible, while the other two were exposed to sandstone dust in special operations not typical of raw mill atmosphere. The occurrence of tuberculosis and chronic infections of the lungs was found to be less frequent than among the general population. The manifestations of tuberculosis occurred in typical form and at the same age periods as in persons not exposed to dust by occupation. It was concluded therefore that prolonged inhalation of cement dust has no unfavorable influence on susceptibility to tuberculous infection or its subsequent evolution.

Digestion Time of Homogenized or Puréed Vegetables.

—Killian and Oclassen determined the advantages and limitations of homogenized fruit and vegetables as supplements to the smooth or bland diet for the treatment of patients with functional disturbances of the gastrointestinal tract. The comparative energy expenditures and the times required for digestion of homogenized and of puréed vegetables in the stomachs of average normal adults and of ambulatory patients with chronic peptic ulcers were studied. According to McLester, these patients require adequate nutrition but at the same time rest, both motor and secretory, for the stomach. Observations are reported on three average normal adults and eight adults with histories of chronic peptic ulcers, confirmed by x-ray examinations before the rates of the digestion of vegetables were determined. In four comparative tests made on the three normal subjects, the average emptying time of the stomach after meals of homogenized vegetables was 43 per cent less than the average emptying time of the stomach after meals of strained vegetables. The average energy expense for gastric digestion of homogenized vegetables, determined in four experiments, was 10 per cent of the fuel value of the vegetables and for digestion of the strained vegetables it was 30 per cent of their fuel values. Gastric evacuation times for homogenized vegetables were less than those for strained or puréed vegetables in six of the eight cases of chronic peptic ulcer. The greatest differences in gastric emptying times for the two forms of vegetables were observed in cases showing pyloric stenosis or retarded gastric motility. The average gastric evacuation time for 300 Gm. of homogenized vegetables was three and a half hours and for 300 Gm. of puréed vegetables it was more than five hours.

Phosphorus and Vitamin D Activity.—O'Brien and Morgareidge observed, under conditions commonly employed for the biologic estimations of vitamin D, that phosphorus added to the vitamin supplement greatly enhances its apparent potency. The equivalent healing is found to be proportional to the product of the vitamin by the phosphorus fed to the rat. For example, 4 mg. of phosphorus daily for eight days (as sodium glycerophosphate) enhances the potency of crystalline vitamin D₂ by 3.4 times. Phosphorus containing compounds do not all possess the same enhancement factor. The significance of this relationship in the estimation of the antirachitic potency of phosphorus containing foods (such as milk) is pointed out.

Medicine, Baltimore

- *Pyelonephritis: Its Relation to Vascular Lesions and to Arterial Hypertension. S. Weiss and F. Parker Jr., Boston.—p. 221.
- Diffuse Arteriolar Disease with Hypertension and Associated Retinal Lesions. H. P. Wagener and N. M. Keith, Rochester, Minn.—p. 317.

Pyelonephritis.—Weiss and Parker summarize the clinical and morphologic features of 100 cases of pyelonephritis in various stages of the disease and report on certain heretofore not well recognized aspects of the disease. Focal pyelonephritis of no clinical significance was not studied. Pyelitis practically never exists unaccompanied by pyelonephritis. Clinically a distinct classification of pyelonephritis as acute, chronic (active), healed or healed and recurrent is often difficult. The structural characteristics of pyelonephritis are essentially the same regardless of the type of infection. In all types (hematogenous, urogenous or lymphatic) marked changes occur in the renal lymphatic system as well as in the nephrons. In chronic and healed pyelonephritis the main morphologic characteristics consist of inflammatory reaction of the interstitial tissues; colloid casts in the tubules, which are lined with atrophic epithelium; periglomerular fibrosis, and evidence of infection or inflammation within the tubules. Pyelonephritis, particularly in the chronic and the healed stages, is often associated with arterial hypertension. The hypertension of pyelonephritis is often severe and is frequently accompanied by nervous symptoms, cerebral encephalopathy, neuroretinitis and high cerebrospinal pressure, and toxemia in pregnancy. The syndrome of left ventricular failure with attacks of cardiac asthma was observed frequently. The hypertension of pyelonephritis can be independent of the activity of renal infection. It often advances when the disease is in the healed stage. Vascular changes occur frequently in pyelonephritis, particularly during the chronic and the healed stages. A relation was found between the severity and diffuseness of the vascular lesions and arterial hypertension. Cases of severe hypertension showed advanced hyperplastic arteriosclerosis, a certain type of productive endarteritis and necrotizing arteriolitis. The correlation between vascular changes and hypertension was close. Vascular changes and hypertension did not occur in the group of cases of renal tuberculosis and hydronephrosis uncomplicated by pyelonephritis. It appears that the inflammatory renal process and the intravascular pressure are responsible for the arterial lesions. In unilateral pyelonephritis, particularly without severe hypertension, the vascular lesions are confined to the affected side. Unilateral pyelonephritis with advanced vascular changes may or may not be associated with hypertension. It is estimated that pyelonephritis is responsible for at least 15 to 20 per cent of malignant hypertension. The vascular lesions in chronic pyelonephritis are restricted mainly

to the kidneys, in contrast to those in "primary" malignant hypertension, which are generalized. Polycystic kidneys, hydro-nephrosis and renal tuberculosis were often complicated by pyelonephritis. Glomerulonephritis and pyelonephritis seldom coexisted. Altered glomerulitis was found in cases with terminal uremia. Pyelonephritis in the chronic and the healed stages should be considered as one type of Bright's disease. The vascular and the renal functional damage are related to the same cause but they may be independent of each other. Chronic and healed pyelonephritis occurs more frequently than chronic glomerulonephritis. Pyelonephritis is one renal disease which can be treated effectively in its incipient stage.

Early Recurrence of Sulfapyridine-Treated Type I Pneumococcus Pneumonia. M. Hamburger Jr. and J. M. Rueggesser, Cincinnati.—p. 445.
Role of Personality in Certain Hypertensive States. T. A. C. Rennie, Baltimore.—p. 448.
Need for Cooperation Between Genito-Urinary and Orthopedic Surgeons. C. J. E. Kieckhefer, Boston.—p. 456.
Pharmacology. G. P. Grabfield, Boston.—p. 464.

Recurrence of Sulfapyridine-Treated Type I Pneumonia.—Hamburger and Rueggesser report the recurrence of type I pneumonia two weeks after apparent recovery following treatment with sulfapyridine. The authors point out that this recurrence is the more unusual as it is the only one to have occurred in the Cincinnati General Hospital in the last three years. During that time more than 1,200 cases of typed pneumococcal pneumonia have been observed. In the case presented the strain of pneumococcus was manifestly sensitive to the action of sulfapyridine, but the defensive forces of the body were presumably not able to bring about the death of all the pneumococci present. The authors have no data that would help to decide whether the organisms remained in the lung, the throat or elsewhere, nor can a new extrinsic infection be absolutely ruled out. However, convalescence took place in a ward in which there had been no other type I patients and in which the patient himself had not been present during his first attack. Data also are lacking concerning the mechanism of recovery from the first attack of pneumonia, but no agglutinins could be demonstrated in the patient's serum after recovery from the second attack. Empyema followed recovery from the second attack, but sulfapyridine was unable to sterilize the pleural cavity even when the exudate was relatively thin. X-ray and physical examinations indicate that little if any of the same pulmonary tissue was involved in both attacks. Further data on sulfapyridine-treated patients is necessary to determine whether the incidence of recurrences of pneumonia by the homologous type pneumococcus is greater in these than in serum-treated patients or in those who recover spontaneously.

Indications for Ligation of Patent Ductus Arteriosus.—Hubbard and his associates show that in evaluating the indications for the surgical treatment of ductus arteriosus many questions arise concerning the prognosis and the complications of this cardiac malformation. The two complications of greatest importance are subacute bacterial endarteritis and congestive failure. The authors conclude that any patient with a diagnosis of patent ductus arteriosus should be carefully studied to determine whether or not there is an arteriovenous shunt large enough to impair the normal cardiac function and the peripheral circulation. The evidence to be looked for is a delay in the growth and development of the child, symptoms of cardiac insufficiency and, more specifically, the signs of free aortic regurgitation, congestion or pulsation of the pulmonary vessels at the hilus of the lung as seen by x-ray examination. Once these symptoms have been established, surgical intervention should be considered in the hope of abolishing the excessive load on the heart, restoring normal circulation, allowing normal growth and eliminating the danger of heart failure. With regard to the possibility of preventing subacute bacterial endarteritis, the situation is uncer-

tain. It will be necessary to observe the successfully treated cases for years before it can be said with conviction that this danger has been removed. If a ligated ductus does remain free of vegetations and if the surgical risk remains as low as now seems possible, it would then, and only then, appear permissible to operate with the expectation of preventing this fatal complication. The optimal age would seem to be in childhood before the second decade, when the incidence of subacute bacterial endarteritis increases, and after the period of infancy. In infancy there is little or no chance of developing this complication and, furthermore, the diagnosis is usually difficult. Two of the cardinal signs of a patent ductus arteriosus, the thrill and characteristic loud continuous murmur, are apt not to be found. In any event a great deal will depend on the surgeon's ability to maintain a low operative risk. The authors think that, until more is known of the operative mortality and the future of the cases already treated, surgical intervention should not be recommended for all patients with a patent ductus arteriosus but should be limited to those showing evidence of circulatory embarrassment.

Sulfanilate for Venereal Lymphogranuloma.—Of fourteen patients with venereal lymphogranuloma in the tertiary stage (diagnosed by a positive Frei test) Hebb and his associates treated eight with sodium sulfanilyl sulfanilate; for two this compound was followed by sodium sulfanilate, and for four with sodium sulfanilate alone. In addition, sodium sulfanilyl sulfanilate was given in four cases of chronic ulcerative colitis. These patients were so treated because of the possibility of this disease being caused by a virus and also as all four failed to respond to usual medication. In the eight cases of venereal lymphogranuloma in which sodium sulfanilyl sulfanilate was administered the average duration of treatment varied from six to thirty-five weeks. Despite this prolonged medication the blood picture was, if anything, improved, particularly in hemoglobin content. The leukocyte count varied somewhat, but there was no indication of bone marrow destruction. Successive treatment of the two cases, first with sodium sulfanilyl sulfanilate and then with sodium sulfanilate because of lack of tolerance of the former drug, resulted in an alteration in the blood picture in one case: the leukocytes were reduced from 5,500 to a low count of 3,650, 56 per cent of which were polymorphonuclears. There is no indication of abnormal cells at present. Two of the four patients given sodium sulfanilate were cured, treatment being continued for twelve and fourteen weeks, respectively. Treatment in all the fourteen cases was followed by general improvement in health, increased appetite, increase in weight and the absorption of strictural tissue. The mechanism of cure and general improvement in health is purely speculative and yet it may be assumed that both drugs cause destruction of the virus and that absorption of strictural tissue with return to normal intestinal function follows the destruction of the infective agent. The four cases of ulcerative colitis apparently responded to sodium sulfanilyl sulfanilate, suggesting the possibility that this disease may be caused by a virus. A larger series of patients so treated must be studied before its general use can be advocated. The intravenous route of injection has been used throughout in these reported cases. However, three other patients have been given sodium sulfanilate orally; 12 Gm. a day was given in four divided doses every four hours. Results

in these cases would indicate that oral administration would be at least as effective as intravenous injection, and perhaps the method of choice. The reactions obtained from intravenous or oral administration were similar to those with sulfanilamide but not as severe. Whatever the route of medication, blood studies should be made at frequent intervals and, if signs of cell degeneration occur, the dose should be reduced or the drug discontinued until the blood picture becomes normal. Cure or great improvement appeared in all. This was indicated by cessation of the bloody purulent discharge, the disappearance of the fistulas or lymphoid nodules and absorption of the rectal stricture. Four of the cases, in which colostomy had previously been performed with no improvement, responded to treatment with closure and healing of the colostomy and the restoration of normal intestinal function.

Acute Cholecystitis.—Glenn reviews the histories of the 219 patients with acute cholecystitis who have been treated at the New York Hospital in the last six years. Early operation is not difficult, it was not attended by a greater incidence of complications nor was the mortality higher than that ordinarily reported for operative diseases of the gallbladder. The outcome of an inflammatory process in the gallbladder is unpredictable. Therefore delay in operating may lead to serious complications, which greatly increase the difficulty of operation and the attendant mortality. The younger the patient when subjected to operation, the better the chance of an uneventful recovery and good end result. On the basis of his observations the author recommends that disease of the biliary tract be treated surgically as soon as the diagnosis is made unless the general condition of the patient makes such treatment dangerous without preoperative therapy. If this policy is pursued, he believes that the mortality rate in surgery of acute cholecystitis will be diminished and, perhaps, the progress of certain systemic diseases, such as cardiovascular and hypertensive disease, may be retarded.

Use of Silk in Thyroid Surgery.—Dunphy and Botsford state that a study of the factors involved in the healing of more than 600 thyroidectomy wounds reveals that, when fine silk was used instead of catgut, the incidence of nonsuppurative wound complication was reduced from 40 to less than 15 per cent and the incidence of suppurative complications from 3.2 to 0.38 per cent. Suppurative complications were more frequent in the cases in which drainage of the wound was employed. There were no infections following thyroidectomy when fine silk was used and the wound closed primarily. No other factor produced so favorable an influence on wound healing as the use of fine

silk. Comparable results were not obtained with catgut even when a careful technic was followed. Postoperative discomfort (tenderness, swelling and induration of the wound) is minimized and consequently the period of morbidity is shortened when silk is used and also the hospital stay is about three days less. Patients are generally discharged from the hospital without a wound dressing when silk is used, and probings after discharge are seldom necessary.

Intraspinal Causes of Low Back and Sciatic Pain.—In sixty consecutive lumbar laminectomies performed for the relief of low back and sciatic pain, Bradford and Spurling found that the gross and microscopic observations fall into four groups: thirty-five cases of herniated nucleus pulposus, thirteen of hypertrophy of the ligamentum flavum, three of true neoplasms and nine negative surgical explorations. Disability was more apparent in the cases of herniated nucleus pulposus and hypertrophied ligamentum flavum than in the negative group. Pain throughout the distribution of the sciatic nerve, although at times secondary in severity to back pain, was present in 88 per cent of the cases of herniated nucleus pulposus and hypertrophied ligamentum flavum, while it was present in only 33 per cent of the negative explorations. Therefore it seems that low back pain indicates an intraspinal lesion only when accompanied by sciatic pain. In 60 per cent of the cases of herniated nucleus pulposus there was hypesthesia or anesthesia limited to the lateral aspect of the leg or foot or both. In contrast, the cases of hypertrophied ligamentum flavum and the negative group showed areas of hypesthesia elsewhere, but in only 15 per cent and 11 per cent, respectively, was hypesthesia limited to these areas. The immediate as well as the final result in twenty-six of the thirty-five cases of herniated nucleus pulposus was excellent. Improvement was slow in seven cases but with definite relief of the more severe pain which had occurred before operation. One patient died too soon after operation to judge whether or not there was any relief, and one patient, who was relieved completely of his pain, died on the twelfth postoperative day. The longest postoperative period through which a patient has been followed is eighteen months, the shortest six months. Therefore the eventual results may not be the same as they appear at present. In the hypertrophied ligamentum flavum group one patient died from meningitis following operation. Of the surviving twelve patients, eight recovered completely and four have slight residual pain but are much improved over their preoperative state. The longest postoperative period in this group is two and one-half years, the shortest six months. Two of the three patients with neoplasms recovered completely and have remained well. The third continues to have mild discomfort in the region of the sacrum, presumably owing to incomplete removal of the dermoid tumor. Four of the nine patients in whom the explorations were negative were relieved almost immediately by the operation and four more have improved slowly. Six of the nine patients are at present free from symptoms, two are moderately improved and in one case there has been no modification in the patient's severe back pain. The diagnosis of herniated nucleus pulposus or hypertrophied ligamentum flavum must be made clinically as well as roentgenologically to assure successful selection of cases for operation. The use of 2 cc. of iodized oil intraspinally is a safe procedure and the amount is adequate for diagnosis.

Sodium Diphenyl Hydantoinate for Epilepsy.—McCartan and Carson report the use of sodium diphenyl hydantoinate for nineteen adults with the grand mal type of epilepsy and for one child with petit mal attacks. All but two of the nineteen showed considerable intellectual deterioration or were mentally defective. In fifteen cases of the major type a complete cessation of fits occurred; there was a decrease in the number of fits in two cases and a slight decrease in the other two. In the case of petit mal (confirmed by electro-encephalography) the fits were slight and lasted only a few seconds, consisting of conjugate deviation of the eyes and loss of touch with the surroundings. The patient was given 0.1 Gm. of the drug twice a day for one month, and there appeared to be some slight improvement; but he then complained of dizziness, and the treatment was stopped and a tonic given. His condition improved immediately, and, apart from his feeling much better now than for some time past, the fits have been much less frequent. These results are better than those given by Putnam and Merritt and may not be borne out over a longer period. The improvement in behavior is striking. Irritability and violent episodes are diminished in frequency and severity. The patients are bright and alert, and there is a subjective feeling of well-being. Even the more deteriorated patients have commented spontaneously on the change and have expressed their gratitude for the treatment. Indeed this is so definite that the drug possibly tends to elate slightly. The undeteriorated patients comment on their increased efficiency and particularly on the absence of drowsiness, which they experienced on bromide and phenobarbital treatment. Toxic symptoms occurred in eight patients and were similar to those described by Putnam and Merritt. In addition to the blood examination carried out before treatment was commenced, a comprehensive blood count has been done at about fortnightly intervals in every case. There is a slight progressive diminution in the erythrocyte count, accompanied by a proportionate fall in the packed cell volume, so that the mean corpuscular volume is unchanged and there is no tendency to macrocytosis. There is no significant change in the hemoglobin content. On the whole there is a slight tendency to lowering of the leukocyte count, and this is due to a fall in the granulocytes. No alteration in the blood picture followed the development of toxic symptoms, apart from an eosinophil increase. It appears that the drug has a slight depressant effect on the hematopoietic marrow; further investigation is necessary to show whether this is progressive, but so far aplastic anemia has not been diagnosed. These blood changes are not sufficiently serious to discourage the use of the drug, but they emphasize the advisability of carrying out frequent blood counts on those under treatment. A curious phenomenon observed in a number of cases was a progressive and marked fall in the blood sedimentation rate. This was not constant throughout the series but did occur in the majority of cases. The authors can offer no explanation for this phenomenon.

Nutritive Value of Powdered Whole Milk.—Hutchinson determined the nutritive value of a popular brand of powdered whole milk which is prepared in Australia from fresh Australian milk. In many parts of Australia it is no more expensive than fresh milk, and its keeping qualities are excellent. It was on samples of this product, bought in the open market, that the study was performed. The milk powder was reconstituted by the addition of the amount of water recommended in the directions. Compared with fresh milk, the reconstituted milk had a somewhat bleached appearance and a flat, slightly cooked taste. The flat taste was partly due to the absence of dissolved gases, for when the milk was shaken for at least thirty minutes in a glass jar and the lid was removed several times during the process, so that more fresh air was allowed to come into contact with the milk, the flavor was improved. The characteristic milky odor was a little more pronounced than in fresh milk. It was found that its nutritive value, compared both chemically and biologically with that of fresh whole milk, although not replacing the latter was an excellent substitute and in some of its properties was even superior.

Menarche and Sterility.—After reviewing earlier reports on the relationship between the menarche and sterility, Mukuda and Horie, in order to obtain information about this problem, conducted inquiries among the outpatients of the obstetric and gynecologic institute of the University of Kyoto. Their material consisted of several thousand cases. They found that in the sterile women the average age of the menarche was 14 years and 11½ months. This is only slightly later than the general average for Japanese women. At first glance this appears to contradict the view that sterility is especially frequent in women with a late menarche. However, detailed inquiry revealed that this is due to the fact that there are comparatively few women whose menarche is delayed. In grouping the women according to their age of menarche and then determining the incidence of sterility in each group, the authors found that the rate of sterility is relatively low in the women in whom the menarche was early but that it increases as the menarche is delayed. The incidence of sterility is especially high in the women in whom the menarche is delayed beyond the age of 17 years.

 Intra-Uterine Fetal Respiration. M. D. Fenning.—p. 87.

Hypoglycemia by Hyperinsulinism in the Newborn.—Rambert thinks that the hypoglycemic accidents of the newborn which are brought on by excessive functioning of the islands of Langerhans are not given sufficient attention. These hypoglycemic accidents occur mostly in the newborn infants of diabetic mothers. These infants present a syndrome of hyperinsulinism comparable to the syndrome of langerhansian adenoma in adults. The hyperinsulinism is a defense reaction of the fetus to the maternal hyperglycemia. Its symptoms may be readily misconstrued and as a result the proper treatment may be withheld with possibly fatal results for the infant. The symptomatology is not characteristic, but the symptoms noted most frequently are cyanosis and convulsions. Cyanosis is usually the first to appear; it increases rapidly and is accompanied by respiratory disturbances. However, in some cases the coloration remains normal. Agitation is frequently observed and it is accompanied by hypotonia, flaccidity, nystagmus, trembling of the extremities and especially convulsive attacks. There are no cardiac disturbances, but in some cases the clinical aspects are those of collapse with pallor, sweats and a comatose state. Since the symptomatology is not typical, the diagnosis would be extremely difficult were it not for three factors: (1) the hyperinsulinism usually occurs in the infants of mothers with severe diabetes, (2) hypoglycemia can be observed in the infants during the postnatal hours and (3) the administration of dextrose generally arrests the symptoms, especially the cyanosis and the convulsions. The evolution of the hypoglycemia in the newborn depends to a large extent on the promptness of the treatment. However, the ultimate prognosis depends on whether hyperplastic lesions exist in the pancreas or whether the disorder is merely functional. The simple administration of dextrose solution makes possible a definite and complete cure in a great number of cases, at least in those in which the disorder is only functional. The injection of dextrose may have to be repeated in cases in which the hypoglycemic attacks recur. Epinephrine and maternal blood have been employed as adjuvants and, in case of cyanosis, inhalation of an oxygen-carbon dioxide mixture has been found helpful.

 *Changes of Electrocardiogram Brought About by Fear. F. Mainzer and M. Krause.—p. 286.

Fear as Cause of Electrocardiographic Changes.—Mainzer and Krause say that aside from the influence of fear on the cardiac rate, which is known from everyday experience, strong fear may induce considerable changes in the electrocardiogram. They observed such fear-induced electrocardiographic changes in the course of studies on the effect of anesthetics on the electrocardiogram. They took electrocardiographic records on the day before the operation, immediately before anesthesia was induced, once or several times during narcosis and again one or several days subsequent to operation. The patients on whom the observations were made were chosen at random from the surgical and gynecologic departments. The three classic leads were taken and the instrument used for this was an amplifier electrocardiograph. The electrocardiograms taken after the patients had been placed on the operating table, when compared with those taken the day before, showed in some of the patients insignificant deviations. These minor deviations are disregarded by the authors. In five patients without cardiac disturbances, the electrocardiographic records taken on the operating table showed considerable changes in comparison with those taken the day before. The authors regard these curves as pathologic and think that the changes were due to fear, for

the fear of the impending operation was quite evident in these patients. The authors differentiate two groups of changes. The characteristic features of the first group were that the ST descended below the iso-electric level and that the T deflection was reversed, which makes these electrocardiograms similar to those found in coronary insufficiency. The characteristic changes of the second group of electrocardiograms were increased amplitude of P and T and a more pointed outline of these two deflections. These electrocardiographic records resembled those of thyrotoxic conditions. As mentioned before, all these patients were highly irritable and overanxious regarding the impending operation. Other possible influences on the configuration of the electrocardiogram, as the effect of drugs, physical exertion and changes of posture, could be excluded. It is noteworthy that the mere elimination of consciousness through anesthesia repeatedly caused the curve to become similar to the original one. It can therefore be regarded as proved that fear, even in persons without cardiac disturbances, may produce considerable changes of the electrocardiogram. As far as it is permitted to draw a conclusion from the form of the electrocardiogram it seems probable that it is either the influence of the nervous excitement on the contraction of the heart muscle (by way of the sympathetic nerve) that predominates (group 2) or the (vagal) effect on the coronary circulation (group 1). The authors observed fear-induced electrocardiographic changes also in two patients with cardiac disturbances and found that in these they were especially severe. They conclude that a knowledge of such fear-induced electrocardiographic changes is important in order to avoid incorrect diagnosis of organic heart disease.

Schweizerische medizinische Wochenschrift, Basel

- Enervation of the Kidney. E. Wildbolz.—p. 825.
 *Hiatus Hernia. E. Biro.—p. 830.
 *Early Diagnosis of Uterocervical Carcinomas by Means of Menstruation Calendars and Blood Curves. T. Marti.—p. 832.
 Bromine Content in Blood of Human Body. J. Karp and Gerda Wolfsohn.—p. 834.

Hiatus Hernia.—Biro gives a clinical description of five cases of hiatus hernia (age of patients between 51 and 63 years; sex not differentiated). These cases were selected from a large number not because of their exceptional character but because they illustrated, according to the author, the diagnostic difficulties of hernia detection in the initial stages, which usually elude the observation of the general practitioner. Roentgenographic discovery of hiatus is best effected with the patient in the recumbent position, head downward, stomach full and during inspiration. Much experience is needed and a trained eye to note suspicious conditions. One of the greatest difficulties is the presence of tonus fluctuations of the cardia in the same individual within a short period, in consequence of which temporary protrusion does not occur. According to the author, hiatus hernia does not constitute a disease entity but is secondary to other morbid conditions. It is of frequent occurrence.

Individual Menstruation Calendars.—Marti reports the use of menstruation calendars and blood curves as employed in the gynecologic division of the university clinics in Geneva. These calendars, simplified adaptations of Kaltenbach's and De Seigneux's blood curve ideas, are regarded as diagnostically valuable for the detection of initial uterocervical carcinomas, since they enable prompt evaluation of atypical and irregular hemorrhages and the early recourse to colposcopy and Schiller's test. The cards, measuring 15 by 11 cm. (about 6 by 4 inches) are issued for one year's use and reissued at the end of the year. The principal side contains the name, age, address, consultation hours of the clinics and sundry information on the significance of menstrual irregularities, the avoidance of self medication, the need of seeking medical counsel at an early date, even though no pain is experienced, and so on. The reverse side bears the calendar for the year. The bearer of this calendar merely crosses the days when her period occurred as well as those on which she observed the slightest atypical discharge. She brings the card with her when consulting the clinics, at which time her menstrual notations are transferred to the blood curve records kept by the clinics. The author thinks that the cause of individual and public health would be served by issuance of menstruation cards to adolescent girls in connection with

hygiene instruction in the schools and by their adoption by the medical profession, the more so as women are notoriously careless in noting hemorrhagic abnormalities and too prone to resort to self medication on dubious advice.

Cystic Adenoma of Kidney of Complicated Structure: Case. A. Scalfi. —p. 559.

*Main Principles of Surgical Treatment of Suppuration of Lung. S. Bigli. —p. 623.

Surgical Treatment in Suppuration of Lung.—According to Bigli, all forms of suppuration of the lung which are not controlled by administration of medical treatment within the first eight or twelve weeks of evolution call for surgical intervention. The author reports nine cases of suppuration of the lung, of various forms. He found that suppuration of the lung with multiple separate abscess is grave and has a tendency to chronicity. Chronic suppuration of the lung involves large territories of the parenchyma in a process of diffuse pyosclerosis and is complicated by secondary bronchiectasia with abscesses. Simple pulmonary abscesses which follow bronchial or pulmonary infections may be either solitary or multiple. Simple abscesses frequently evolve to solitary or multiple putrid abscesses which are clinically different from gangrenous abscess of the lung. The treatment of well circumscribed abscesses is as follows: pneumonectomy with detersion of the cavity of the abscess in simple solitary and simple multiple abscesses, and pneumonectomy with more or less ample resection of necrotic tissues followed by drainage with medicated gauze in simple putrid and multiple putrid abscesses. The operation is performed once in cases of solitary abscesses and it is repeated in cases of multiple abscesses. In cases of central, paralobar and deeply located abscesses the operation consists of paraffin plugging, which is followed in twelve days by pneumonectomy. Cortical abscesses call for an early pneumonectomy because of the fact that they are a menace and may either invade the pleura or rupture into it. In either case the treatment consists of pleurotomy followed by ample drainage. The surgical treatment of gangrenous abscesses gives satisfactory results only when it is resorted to early in the development of the abscess. It consists of repeated pneumonectomy and resection. The author concludes by calling attention to the importance of early x-ray diagnosis and early surgical treatment.

Distribution of Tetanus Toxin in Animal Body.—Bromeis attempted to determine in experiments on guinea pigs and mice the proportion of tetanus toxin carried to the central nervous system directly by the regional motor nerve and that part which is first transported by the lymph and blood to the rest of the motor nerves and is then carried by them to the central nervous system. This was accomplished by injecting massive doses of the toxin, estimating the amount found in the regional motor nerve; by extirpating the depots of toxin and determining the amount contained in them by injections into mice; by estimating the amount found in the motor nerves away from the seat of the injections, and lastly by subtracting the toxin that has not been taken up by the nerves. It was found that the regional motor nerve takes up about two thirds of the injected toxin, while the remaining third is first carried by lymph and blood to other motor nerves to be transported by them to the central nervous system. The absorption of the toxin by the regional nerve takes place within the first hour after the injection and travels along the nerve toward the central nervous system at about the rate of 1 cm. an hour. The greater part of the incubation period (from one half to two thirds) is consumed by the process of combining the toxin molecule with the nerve cells of the spinal cord. The time occupied by the

transport of the toxin to the central nervous system constitutes a small fraction of the incubation period. The time required for the manifestation of symptoms after the bacillary infection amounts to from one day to one third of the entire incubation period, depending on the virulence of the bacillus and the local conditions. The prophylactic dose of antitoxin may therefore still be effective if given in larger doses on the second or third day of the trauma. His experiments, the author feels, not only do not negate the value of antitoxin but indicate the rationale of administering it at the earliest moment and in maximum doses. This is best accomplished by intravenous injections and local injection into the tissues between the wound and the regional motor nerve.

Influence of Pregnancy and Lactation on Mammary Cancer.—On the basis of 2,000 cases of mammary carcinoma and of 1,500 cases of carcinoma of other parts in female patients observed in the Tübingen clinic between 1911 and 1935, as well as on the observations of other authors and on his own experimental studies, Bromeis attempts to determine the influence of pregnancy and lactation on mammary cancer. It appears from his study that pregnancy and lactation exert the very opposite effect on carcinoma and that the incidence and the degree of malignancy of the cancer find themselves in the same relationship. Nulliparas and, even more so, women who do not nurse are more liable to the development of mammary carcinoma than others even though the carcinoma in their instance is somewhat less malignant. A large number of childbirths is likely, however, to increase the incidence and the malignancy of a later cancer because of the greater possibility of lactation alterations within the breast. Cancer of the breast develops exceptionally only in the course of a pregnancy but is then unusually malignant, the last months of pregnancy having a particularly unfavorable influence on the neoplasm. The exceptionally high-grade malignant condition here is not explainable on the basis of the patient's youth. An intervening pregnancy likewise exerts an unfavorable influence on the neoplasm. The latter, however, is not nearly as malignant as that which develops in the course of a pregnancy. Mammary cancers arising after childbirth are much more frequent but are less malignant, especially if lactation is practiced. Lactation appears to have a beneficial influence on the existing mammary cancer. Malignant transformation of a benign mammary tumor is particularly frequent in the lactation period. Bromeis was able to demonstrate in experiments on mice that pregnancy stimulates the growth of a carcinoma and that lactation retards it. The incidence of recurrences in animal experiments is lessened when pregnancy takes place shortly after operation. The recurrences arise not during the pregnancy but toward the end of the lactation period. In contrast to this, tumors removed in the course of a pregnancy recur with great rapidity. The author injected nucleic acid into tumor mice and obtained the same alterations in their breasts as those observed in pregnancy and lactation. These alterations exerted an influence on the growth of the tumor which paralleled that of pregnancy and of lactation. The former stimulated the growth of the tumor and the latter retarded it. He had also made the observation that more than one fourth of the women with mammary carcinoma were of the type presenting marked developmental weakness of the connective tissue. The hormonal influence of pregnancy and lactation was not clear. In his opinion a radical operation for mammary cancer without interruption of pregnancy is permissible within the first two or three months, provided that an early operation is possible and that the biopsy reveals a tumor of average malignancy. In all other instances a radical operation and interruption of pregnancy are indicated up to the third month. Pregnancy should be interrupted during the fourth and fifth months only when the existing mammary carcinoma is easily operated on and the life of the child is not of any particular importance. From the sixth month on, the interruption of pregnancy presents no advantage except that in the interest of prolonging the mother's life induction of labor during the seventh month is indicated. Pregnancy is to be interrupted in all advanced inoperable cases of mammary carcinoma. The termination should precede the radical operation by from two to four weeks. Benign mammary tumors are to be removed in the early stage of pregnancy. They are to be removed at once when observed for the first time during lactation. Castration in pregnant

women with mammary cancer is indicated only in the older patients close to the menopause; in younger women it is sufficient to prevent conception for the next three to five years. Castration is not indicated in cases in which the carcinoma was first recognized during the lactation period. The author likewise feels that sterilization is not to be recommended after a radical operation for mammary carcinoma in a woman during the child bearing period. It is sufficient here to prevent conception for several years and to keep the other breast under observation during, and especially after, a later pregnancy.

*Length of Twins at Birth as Sign of Maturity. W. Wolf.—p. 570.

Length of Twins as Sign of Maturity.—Wolf reports that in the course of a lawsuit on the paternity of twins the question arose whether twins who measured 47.5 and 46.5 cm., respectively, could be born 305 days post cohabitationem. The question was answered in the affirmative with the suggestion that twins are normally always shorter than azygous infants and that they could be born without signs of hypermaturity even after a gestation lasting that long. In view of the forensic importance of this problem, the author investigated the records of 400 twins born during the period from 1908 to 1938. After excluding those cases in which the mother's last menstruation was not definitely stated or the length of her menstrual cycle was irregular, as well as those in which dead or macerated fetuses were born, there remained 160 cases which seemed suitable for this investigation. They were classified in seven groups, depending on the length of gestation. The first group included those born after 231 to 240 days of gestation; the second group those born after 241 to 250 days and so on, the seventh group including those born after 291 to 300 days. The author agrees with Lüdi that for the estimation of the degree of maturity it is best to consider only the length of the longest of the twins. He found that after a gestation of from 270 to 280 days the length of the longest twin varies between 46 and 52 cm., the mean being 49 cm., that is, a length which does not greatly differ from that of azygous infants. The author regards it as extremely rare that twins are carried for longer than 300 days after the last menstruation. However, if they are carried past the normal term they seem to have at least the signs of complete maturity. According to the figures that are available so far, twins that are born before the eighth month of gestation seem to be longer rather than shorter than azygous fetuses that have been carried for the same length of time. This observation contradicts all expectations; however, in view of the small numbers, of the fact that sex of the twins has been disregarded and of other factors, this statement must be evaluated with extreme caution. The author reaches the conclusion that the statement (often made in paternity lawsuits) that twins need not show the signs of maturity after a normal length of pregnancy or may lack the signs of hypermaturity even if carried far beyond the term normally is not justified. Actually the length measurements established as a criterion for the maturity of azygous fetuses apply with slight deviations also to twins.

Hyperinsulinism.—Thomae directs attention to a disease entity which is characterized by hypoglycemic manifestations. Hypoglycemia is observed (1) during adrenal insufficiency (Addison's disease), (2) during hypofunction of the thyroid, that is, during myxedema, (3) during insufficiency of the posterior lobe

of the hypophysis, namely, occasionally during diabetes insipidus and adiposogenital dystrophy, (4) during hypofunction of the anterior lobe of the hypophysis, such as in hypophysial cachexia and (5) during hyperfunction of the insular apparatus (hyperinsulinism) which is due to adenoma or carcinoma of the island cells or to insular hyperplasia. In order to arrive at the diagnosis of spontaneous hypoglycemia it is necessary to exclude disorders of the adrenals, the thyroid and the hypophysis. All earlier studies, especially those of Harris, who first described hyperinsulinism in 1924, brought clarification so far as they differentiated between functional hyperinsulinism, in which no changes are found in the pancreas, and hyperinsulinism, in which there exist changes in the island cells. To be sure, there still remains the problem whether the hypophysis is perhaps responsible for the so-called functional hyperinsulinism. The author describes in detail the history of a patient observed and treated by him. Discussing this case and the multiform symptomatology of hypoglycemia, he directs attention to Josef Wilder's suggested classification of "small," "moderate" and "great" glycopenic attack. The small attack has only few symptoms that are characteristic for hypoglycemia; there are sensations of hunger, sudden sweats and visual disturbances (swimming of objects before the eyes); irritability and quarrelsomeness are occasionally observed; heart action and blood pressure may be decreased or increased; fatigue, somnolence and excessive yawning are quite frequent. The only constant sign is that all these symptoms are counteracted by intake of sugar. The author believes that "small" attacks of hypoglycemia are not always recognized. He thinks that physicians should give more attention to the aforementioned complaints and that medication with sugar might perhaps lead to a correct diagnosis of such symptoms. In "moderate" glycopenic attacks the symptoms are about the same as in the "small attacks" but they are more severe. The "great" attacks are accompanied by threatening collapse and fainting, by temporary paralysis and blindness. Pallor and cold sweats are characteristic for beginning glycopenic coma, and lethargic and stuporous conditions have been observed. In remarks about the therapy of sugar deficiency, the author takes up diet, surgical treatment and treatment with insulin. For the dietetic treatment he recommends numerous small meals with a high carbohydrate content. Surgical treatment is necessary in case of neoplasm of the pancreas. The apparently paradoxical insulin treatment of hyperinsulinism was suggested by H. J. John, who reasoned that the exogenic administration of insulin would induce hypofunction of the insular cells. John recommends a diet with a high fat content and the injection of insulin after every meal. The author says that encouraging results have been obtained with this treatment and points out that Harris likewise attempted to reduce insulin production by diets with a high fat content. In the conclusion he expresses the opinion that glycopenic attacks are more frequent than they are diagnosed. He thinks that the sugar metabolism should be investigated of patients with repeated attacks of fainting as well as of persons, particularly children, who are easily fatigued.

*Treatment of Delirium Tremens. G. Säker.—p. 410.

Treatment of Delirium Tremens.—Säker directs attention to the fact that chronic alcoholism and delirium tremens are accompanied by impairment of the liver and that this hepatic disturbance can be influenced by treatment with insulin and dextrose provided anatomic changes do not prevent it. He says that Kral and his collaborators observed a favorable effect of this insulin therapy in chronic alcoholism. Moreover, they found that it has a sedative and an abridging effect on the delirium. The author, however, by giving twice from 5 to 10 units of insulin and dextrose, did not observe these effects on the delirium but did observe a favorable effect on predelinous, pseudoneurasthenic conditions and noted an accelerated disappearance of the psychosomatic symptoms that remained after the delirium. In two cases of delirium tremens he attempted to obtain results with preliminary shocks induced by means of insulin. In the first case a threatening circulatory collapse which

did not yield to cardiac and circulatory remedies could be counteracted by preliminary insulin shock. In the second case a severe delirium could be counteracted by preliminary insulin shock without resort to cardiac remedies or narcotics. Both of these patients presented a relative insensibility to insulin in that comparatively high doses were necessary to induce insulin shock. It is noteworthy that the gradual transition from preliminary shock to true shock was lacking and that only the deep shock interrupted the delirium. It is also interesting that the hallucinations and other signs of delirium disappeared only at the threshold of deep shock and that they reappeared when the shock was interrupted by means of dextrose. The improvement in the circulation, however, was effected before the shock. The author does not recommend this treatment for general use in delirium tremens because the delirium is not noticeably shortened by it and it is not without danger, but he thinks that it could be tried as a last resort in especially severe cases. He further discusses the use of vitamin B₁ in chronic alcoholism and its complications and expresses the hope that the further development of the insulin, dextrose and vitamin B₁ therapies will lead to a causal therapy of alcoholism and especially of delirium tremens.

Urinary Trichomoniasis in Women.—According to Rodecurt, in cystitis, ureteritis and pyelitis the possibility of infestation with *Trichomonas* is rarely considered. The female urethra harbors *Trichomonas* more frequently than is generally assumed. The majority of women with urinary trichomoniasis have simultaneously a vaginal or cervical leukorrhea, frequently combined with vulvitis, colpitis or erosions of the cervix, or they previously have had a nongonorrheal discharge. Primary trichomoniasis of the urethra is rare; more rarely still does trichomoniasis remain restricted to this organ or the urinary tract. The presence of *Trichomonas* does not necessarily cause symptoms. The infection may remain latent for a long period until symptoms are elicited by such factors as colds or catheterization. The subjective symptoms of urinary trichomoniasis are not characteristic. The patients may complain of burning or piercing pains in the urethra, frequent urge to urinate and vesical pains. A discharge from the urethra is usually overlooked or mistaken for a vaginal discharge, the vagina being nearly always more or less involved. Inspection of the external orifice of the urethra usually reveals nothing abnormal. In acute cases there may be reddishness, swelling and a white-yellow-greenish discharge from the urethra and perhaps also from the vagina. If the trichomoniasis is limited to the urethra, the examination of the urine for protein is usually negative. The fact that the catheter urine is entirely clear does not exclude the possibility of an infection with flagellates. Examination of the urethra may disclose nothing but a slight irritation, which may be ascribed to the mechanical manipulations involved in the examination or may be interpreted as "irritable bladder" or the nervous symptom of cystitis. It is characteristic for infection with *Trichomonas* that psycho-antineurotic therapy or the application of heat exerts no influence. Even urinary disinfectants and the remedies used for vesical lavage are ineffective. The diagnosis of trichomoniasis can be based only on repeated, careful examinations of urethral slide preparations. Following remarks about the technic of the examination, the author says that in the local treatment of trichomoniasis of the urethra he obtained the best results with a 3 per cent aqueous solution of chiniofon. He applies this solution by means of a tampon holder. Following saturation of the tampon, it is introduced into the urethra and is left there for about ninety seconds. This treatment is given every second day, at least twelve times. The genitalia must be treated simultaneously with the urethra. In cases of mixed infections, the customary urologic therapy must be added.

Pathogenicity of *Spirochaeta Pallida*.—Grigoriev, working in the laboratory of the First Medical Institute of Moscow, claims to have succeeded in growing a pure culture of *Spirochaeta pallida*. Blood was taken from a vein of a patient with a diagnosis of primary serum negative syphilis and cultured on the Tarozzi medium. The patient gave a positive reaction three weeks later. No spirochetes were detected fourteen days after culture. However, reculturing yielded, six days later, a great number of typical spirochetes. This first "Moscow" strain was recultured every eight days and has yielded thus far thirty-eight generations. Intravenous injection of the pure culture caused in rabbits the appearance of typical primary lesions which contained numerous typical spirochetes. The passage of cultures in rabbits had the effect of increasing their pathogenicity. The passage of infected material from rabbits through white mice likewise did not attenuate the virulence of the organisms. The author believes that his cultures may be utilized for the preparation of antigen and for therapeutic and preventive vaccines.

 So-Called Morbilli Bullosi. J. L. Keyser.—p. 437.
 Granulocytopenia. J. C. Schippers.—p. 450.

Treatment with Massive Dose of Vitamin D.—Van Ormondt reviews the literature on the treatment of rickets with a single large dose of vitamin D as well as on the prophylactic administration of a massive dose. This review indicates that rickets can be cured with a dose of 15 mg., that is 600,000 international units of vitamin D. Vitamin D₂ as well as D₃ can be used for this purpose. For the prophylaxis of rickets, from 7 to 10 mg. of vitamin D is sufficient. After discussing the indication for this so-called vitamin D "shock" therapy and vitamin D "shock" prophylaxis, the author describes three severe cases of rickets in which favorable results were obtained with this treatment. She says that in these cases improvement started later than in those reported in the literature and thinks that this is due to the fact that the required dose was given in two injections, with an interval of two or three weeks, rather than in a single dose. The treatment caused no harmful effects. In view of the great number of good results and the absence of symptoms of hypervitaminosis, vitamin D shock therapy and vitamin D shock prophylaxis can be considered a valuable addition to the therapeutic armamentarium of rickets. The author thinks that the vitamin D shock prophylaxis should be used more generally in cases in which prophylaxis with repeated small doses is difficult.

 *Acetonemia in Pregnancy. E. Tonkes.—p. 4216.
 Conglomerate Tubercle in Spinal Cord. E. Hoelen and J. Tans.—p. 4223.

Acetonemia During Pregnancy.—Tonkes says that it is generally assumed that acetone develops when, in case of insufficiency of carbohydrates, fats must be burned to meet the energy requirements, and that ketone bodies develop also from proteins. He cites investigators who demonstrated that during pregnancy the acetone content is generally higher than is the case outside of pregnancy and that in pregnancies complicated by intoxications the acetone values are still higher. However, that a high acetone content of the blood and acetonuria may exist also in the absence of the well known causes the author demonstrates by means of a case recently observed by him. A woman aged 28, who was pregnant for the second time, had

hyperacetonemia and acetonuria, but no diabetes, hyperemesis or gestosis could be demonstrated as a possible cause. Increase of carbohydrates in the diet did not result in improvement; on the contrary, the acetone values showed a further increase after a diet with a high carbohydrate content had been given for a week. It was now decided to administer twice daily 10 units of insulin together with 100 Gm. of sugar. This combined administration of insulin and sugar produced the desired results. The author suggests that this is a case of the type which Broustet and Mahon referred to as "primary acetonemia of gestation." He also stresses that almost immediately after the administration of insulin the water elimination was greatly increased. He assumes that the hyperacetonemia was caused by a hepatic disturbance and directs attention to the fact that acetonemia plays a part in the intoxications of pregnancy, many investigators having observed increased acetone values in women with gestosis. Pregnancy increases the functional requirements of the liver, and the administration of sugar is an aid in the hepatic function; however, insulin is necessary for the utilization of this sugar. In this connection the author stresses the value of insulin in the treatment of the metabolic disturbances of pregnancy, especially the toxemias of pregnancy.

Metabolism and Cardiac Output in Children.—Plum investigated the mechanism of circulatory impairment in diphtheria. As these studies required control determinations of the normal rate of metabolism and of the cardiac output, the latter were examined first in a number of children who could be regarded as "normal." Summarizing his observations on the metabolism in normal children the author says that he found that the metabolism in children may be determined with about the same degree of accuracy as in adults and that the intensity of the metabolism diminishes greatly with age, both when calculated per weight unit and per surface unit. The metabolism per kilogram of body weight is about twice as great in a child aged $3\frac{1}{2}$ as in a child aged 16. Also when calculated per surface unit the metabolism is found to decrease noticeably with age. In 100 experiments on twenty-two children the respiratory quotient was found to be on an average 0.83, varying between 0.80 and 0.89. Regarding the cardiac output of normal children, the author says that it, like the metabolism, is relatively considerably higher in children than in adults and relatively greater in younger than in older children. The tissues of a child aged 4 years are supplied with about twice as much blood per weight unit as are the tissues of a child aged 16. The arteriovenous oxygen difference is independent of the age of the subject and is the same in children as in adults. Attention is called to the fact that, in spite of their more intensive metabolism, children show no greater arteriovenous oxygen difference than do adults and that their circulation therefore in this respect possesses the same reserve force as that of adults, notwithstanding the relatively greater cardiac output. Summarizing his observations on the circulation and metabolism of children with diphtheria, the author says that the arteriovenous oxygen difference and the cardiac output were found to lie within normal limits throughout the disease. The skin temperature in the lower extremities was decreased during the stage of acute impairment of the circulation. Capillary microscopy showed decreased circulation in the capillaries of the skin. The metabolism was slightly decreased immediately after the cessation of the fever. The respiratory quotient was found to

be low in the febrile stage of the disease. These observations suggest that an essential cause of the circulatory impairment in diphtheria is to be found in paralysis of the peripheral vascular system, especially the splanchnic blood vessels. Whether myocardial changes are likely to bring about a fatal outcome cannot be decided at present.

Pain at Distance from Heart in Coronary Insufficiency.—Mainzer says that since Heberden the paroxysmal pain of angina pectoris radiating into the left or (more rarely) right shoulder and arm has been the object of intensive investigation. A considerable number of unusual types of radiating pain have since been observed. All these types of pain, however, have this in common, that they occur in paroxysms and are usually accompanied by manifestations of the heart itself (sensation of constriction, dyspnea, "heart pain" and so on). In this report, however, Mainzer directs attention to another type of pain, which is felt at a distance from the heart but which is equally associated with coronary insufficiency and must be carefully distinguished from that paroxysmal pain which occurs in angina pectoris. He considers cases in which during the period of pain there are no symptoms which can be connected with the heart itself. If the pain, which may be severe and may persist over weeks, occurs in a case in which the history shows coronary insufficiency, the diagnosis is not so difficult. If, on the other hand, the pain precedes the symptoms of coronary insufficiency, great difficulty is encountered in its classification and treatment. The author reports five cases in which coronary insufficiency occurred and isolated persistent pain was felt at a distance from the heart, namely in a shoulder or in the epigastric region. The pain persisted for weeks. Examination disclosed no local cause nor was the pain connected with circulatory symptoms. Four of the patients had myocardial infarction. The persistent pain came on either previously or subsequently to the infarction, but always separated from this event by a considerable time. Its localization was in every instance identical with that of the radiating pain during the infarction. This fact as well as the absence of any local lesions in the painful area indicates a causal relationship between coronary insufficiency and the pain syndrome. Another patient had a similar pain in the right shoulder. This patient had been suffering from aortic incompetence without angina pectoris, the coronary insufficiency becoming apparent by disturbances of the cardiac rhythm.

Esophageal Spasm as Cardiac Symptom.—Wahlberg reports three cases in which esophageal spasm occurred with cardiac decompensation. The first patient complained that for the last three days swallowing had been accompanied by pains behind the lower part of the sternum and the other two patients had similar complaints. The connection between the cardiac disturbance and the esophageal spasm was evident in all cases and in two of them it could be demonstrated by roentgenoscopy. The ages of the patients were 72, 69 and 76, respectively, and all three had peripheral arteriosclerosis. The first patient had a new cardiac infarct, the second one a chronic cardiac and coronary insufficiency and the third one a chronic cardiac insufficiency without signs of disturbance of the coronary circulation. The last two cases were in a stage of acute exacerbation. The author thinks that on the basis of his observations esophageal spasm can be classified with the symptoms that may develop in cardiac insufficiency. This small number of cases seems to indicate that relatively advanced age, severe peripheral arteriosclerosis and possibly also disturbances in the coronary circulation are predisposing factors. The esophageal spasm is of practical significance in that in its presence it is advisable to refrain from the diagnosis malignant tumor of the esophagus until careful examination and observation have ruled out a possible cardiac origin. The pathogenesis of esophageal spasm as a cardiac symptom is not readily explainable. X-ray examination in the author's cases indicated that mechanical pressure from cardiac or aortic dilatation played no part as an eliciting factor. The author thinks that it is necessary to postulate a visceral reflex mechanism from heart to esophagus by way of the sympathetic. In this connection he points out that the tonus of the esophagus is supposedly regulated by the sympathetic and that it has been demonstrated that lesions of the cervical sympathetic may elicit esophageal spasm. Finally it is known what dominating part is played by the cervical sympathetic in the elicitation of the pain in coronary disease.

SATURDAY, NOVEMBER 25, 1939

STUDY OF ATTITUDES, PERSONALITY, SOCIAL FITNESS, ADAPTABILITY, CHARACTER AND MOTIVATIONS OF MEDICAL STUDENTS

NORMAN R. FIELDER, M.A.

Program Director, West Side Professional Schools
Department, Y. M. C. A.

CHICAGO

The inter-medical schools council composed of students in Chicago's West Side medical schools for years has sponsored a program of extracurricular activities. Out of this experience grew an interest in personal and social problems of students which was further intensified by a study of the reactions of students to different types of school activities. In time many problems bearing on the life of medical students were brought into bold relief. Usually the problems concerned student attitudes and beliefs as they related to personal ethics and social issues. Typical questions were:

1. What do medical students expect from their education?
2. Is the general attitude of most medical students selfish?
3. Are most students unwilling to assume more than a minimum amount of responsibility in the conduct of community welfare?
4. Are students for or against greater socialization of all community services?
5. How do students really feel about religion? How do they regard the practices of the organized religious groups?
6. Does the medical student's professional training make him more or less sympathetic with human needs?
7. What does the medical training period do for his moral life?
8. What about his life philosophy?

Valid answers to such questions might be expected to have important relations to the vital personal problems uncovered in the routine academic work of medical students. Members of the inter-medical schools council agreed that an effort should be made to gather reliable information that might afford a sound basis for the study of such problems. A careful study of the activities and interest of medical students of the entire local community was instituted. Encouraged by the outcome in the home community, the council extended the investigation to include a wider field.

THE CLINICS

For the school season of 1939 a new type of activity was planned in the form of a series of student sponsored personal problems clinics. The general theme of the clinics finds its origin in a resolution on medical education adopted in Kansas City at the eighty-seventh annual session of the American Medical Association, which was as follows:

WHEREAS, The relationship between physician and patient embodies many factors that must be considered in the determination of an individual's fitness to be a doctor of medicine; and

WHEREAS, The entrance requirements to the degree of Doctor of Medicine cannot be evaluated on a strictly academic basis; therefore be it

Resolved, That the following factors be considered in the selection of students who are to become doctors: character, personality, social fitness, adaptability and motivations.

PURPOSE OF CLINICS

It is the purpose of the council sponsoring the clinics to deal concretely with personal student problems growing out of the general ideas indicated in the foregoing resolution.

The clinics serve as a focal point in a program designed to meet the growing demand of the large body of medical students for help in finding answers to the complex social, economic, religious and professional problems not touched on in the scientific courses of medical schools.

PROGRAM

Each clinic is under the leadership of a commission of several students and one or more faculty resource persons who, because of their experience, have a contribution to make to the analysis and solution of the problems. The personal problems to be faced by the various commissions have been determined by a series of student surveys and student sponsored questionnaires.

In the work of a clinic group no analysis of a student problem is considered complete

until the following control questions have been answered:

1. What are the actual facts involved, especially the underlying basic factors?
2. What makes this a problem of medical student concern?
3. What proposals are being made or have been made for dealing with this problem? (Be specific.)
4. Is there a recognized professional critique for the solution of this problem? (How is it stated?)
5. If there are generally recognized standards and critique commonly accepted in the judging of issues involved, are they sufficient for fast changing social requirements? (What concrete evidence do you have?)
6. What specific policy and suggestions can be made as the result of the work of this commission and this clinic.

LEADERSHIP

In conjunction with the clinic sessions, special conferences have been held with leaders in the field of medical and professional practice. Here the seasoned medical practitioner, the recognized medical educator and other qualified experts examine the major problems and issues arising out of the student clinics and in their discussions seek to provide guidance and information for the final analysis of such problems. Those who have directed discussions and advised with the student leaders are Dr. David Davis, dean of the University of Illinois College of Medicine; Dr. George E. Waklerlin, University of Illinois College of Medicine; Dr. Morris Fishbein, Editor of *THE JOURNAL*; Dr. Harry A. Overstreet, head of the department of psychology and philosophy at the College of the City of New York; Dr. William H. Welker, University of Illinois College of Medicine; Dr. Howard Sheaff, Rush Medical College; Dr. T. T. Job, Loyola University School of Medicine; Dr. F. L. Lederer, University of Illinois College of Medicine; Dr. Harry Oberhelman, Rush Medical College; Dr. G. B. Hassin, University of Illinois School of Medicine, and Mr. William H. Browne, University of Illinois School of Medicine. Much credit is due to these men for their leadership in the work of the clinics.

POINT OF VIEW OF MEDICAL STUDENTS

Experience in the work of the clinics to date emphasizes the importance of the investigations. More than 600 different students have attended and participated in the clinics; 3,200 different students have returned questionnaires and assisted with the surveys. The following statement seeks to summarize some of the observations:

There is evidence on every hand that an old order is passing. Rapid changes are taking place in the direction of greater social control. Individualism in economics, politics and social practice is being challenged and curbed, while various forms of collectivism are arising all over the world. There is much talk about the value of human personality. What is the real meaning of all this to medical students? Do present day professional training methods make professional leaders sufficiently sensitive to human need?

What is the real meaning of such expressions as Freedom and Responsibility as they pertain to the individual life? In our present social order, must the practicing medical man and woman accept the idea and then live as though freedom and responsibility are one and the same thing? How may the medical student interpret the statement "To live with complete freedom is to take the entire responsibility for one's own life and the lives of others as well." Is it true that students are forever trying to wriggle out of responsibility? What have students to say in answer to the often repeated statement "What so many students want is freedom from responsibility." Isn't it true that the seasoned medical man and woman must accept a great deal of responsibility that can never be paid for in dollars and cents? What is your attitude toward this?

Professional practitioners in the various fields of social service are hearing with growing frequency reference to group and state controlled schemes and plans for social service. Thought provoking questions pertaining to such subjects as socialized medicine, group hospitalization plans and free public clinics are raised and remain only to be unsatisfactorily answered.

Any change in traditional ideas, personal customs and institutions always brings conflict, disorder and general chaos. As graduate students and as medical leaders of tomorrow, students should be deeply concerned about the future.

We believe that we should become thoroughly aware of what is happening in the world today, both for the sake of our own insight and for our ability to interpret the changing social order. We believe that education is meaningful only in relation to the economic, social and personal conditions of the times. We recognize that it is all too easy to acquire a sideline attitude toward important issues—to become satisfied with mere intellectual speculation and to hold ourselves aloof from the realities of social, political, professional and personal problems. Social, health, professional and personal problems take on new meaning in practical application.

As medical students, we are preparing not only to be physicians but also to be active participants in the social life of the community in which we shall live and practice.

THE QUESTIONNAIRE

In order to provide a background for the discussions in the clinics and to establish their proceedings on a reliable basis, questionnaires were formulated and circulated among the students of all the medical schools.

The response to the questionnaires exceeded all expectations. Not only did the replies provide the desired basis of reliable data, but an even more intensive study resulted from this source of student expression and the council has decided to continue the clinics for another year. Eighty-seven per cent of all the questionnaires circulated among the entire enrolment were returned and tabulated. According to the experiments of statisticians, the answers of even one tenth of a group, when it includes several hundred individuals, yields results much like those which would be obtained if every individual in the group had answered, provided no selection in the choice of the one tenth of the group has taken place. But our study was not content to stop with one tenth of the group.

The entire returns were tabulated and the final results represent 87 per cent of the total questionnaires circulated. We feel certain that the tabulations of this high percentage represents a true picture of the general attitudes and beliefs of medical students enrolled in the medical schools on the questions included in the questionnaire.

MEDICAL STUDENTS' QUESTIONNAIRE

Please do not sign your name! Your help is requested in gathering honest information regarding what professional students do and think. The answers to the questions, when compiled, will provide a substantial basis for the discussions of the Medical Students' Problems Clinics, of the West Side Professional Schools Y. M. C. A.

Please be honest. In no way will there be any attempt made to identify you with your answers.

Q.—Sex? Q.—Age? A.—Average 26. Q.—Married? School? Year? Years in college?

Q.—Parents: Profession? Race? Religion? A.—Protestant first, Jewish second, Catholic third.

1. Q.—What are your real reasons for entering the profession for which you are studying? Please number them 1 for most important and 2 for second, and so on.

A.—Easy work —. Social position 4.2%. Chances for marriage —. Taste 30%. Aptitude 3.8%. Opportunity for service 49%. Money 3.8%. Parental pressure —. Advice of others 4.2%.

2. Q.—Do you work outside? A.—65% yes, 35% no. Q.—Do you feel that outside work in moderate amount is a handicap? A.—60% yes, 40% no.

3. Q.—Outside of studies and sleep, what are your principal activities? Please rank them in order of time spent, 1 for first and 2 for second, and so on.

A.—Reading 40%; "Bull sessions" 6%; Drinking —. Opposite sex 2%. Movies 8%; Outside work 44%.

4. Q.—Do you spend time on a hobby? A.—46% do, 54% do not. Q.—If so, what? A.—Photography first, stamp collecting second, books third.

5. Q.—What is your favorite magazine? A.—First choice *Reader's Digest*, second choice *Life Magazine*.

6. Q.—Do you ever stay up the major part of the night to study for an exam? A.—52% do, 48% do not.

7. Q.—Do you follow a regular study schedule? A.—51% yes, 49% no.

8. Q.—Do you ever carry "crib notes" to exams? A.—75% do not, 25% do.

9. Q.—Do you condemn those who do? A.—55% yes, 45% no.

10. Q.—Do you accept information from your neighbors during an exam? A.—30% yes, 70% no.

11. Q.—Do you give such information? A.—56% yes, 44% no.

12. Q.—Do you think the honor system would work in your class? A.—21% yes, 79% no.

13. Q.—Do you always attend classes when attendance is not taken? A.—42% do not, 58% do.

14. Q.—Of your instructors the past term, how many would you rate in each group? A.—Excellent fourth, good third, fair first, poor second.

15. Q.—Please number, in order of importance, the characteristics you believe an ideal instructor in your professional school should have. A.—Technical knowledge first, pleasing personality first, clarity of expression first, clear speaking second, general information third, lucid thinking fourth and research ability fifth.

16. Q.—Do you feel that the students in your class are overworked? A.—60% yes, 40% no.

17. Q.—Should an instructor take his personal opinion of a student's suitability to a profession into consideration when passing him or failing him? A.—70% no, 30% yes.

18. Q.—If it were legal, would you perform abortions on unmarried women? A.—68% yes, 32% no.

19. Q.—Would you tell "white lies" to patients? A.—98% yes, 2% no.

20. Q.—Would you do plastic surgery for beauty's sake? A.—64% yes, 36% no.

21. Q.—Do you believe in "mercy deaths" in incurable disease? A.—22% yes, 78% no.

22. Q.—Has your professional school made you more aware of human need? A.—74% yes, 26% no.

23. Q.—Of what political faith are your parents? With what political faith do you now sympathize?

21. Q.—Do you believe in government control of production? A.—84% no, 16% yes.

25. Q.—Are you prejudiced against Jews? A.—22% yes, 78% no. Q.—Are you prejudiced against Gentiles? A.—94% no, 6% yes.

26. Q.—Would you date a person of a different race? A.—80% yes, 20% no. Q.—Marry one? A.—95% no, 5% yes. Q.—Room with one? A.—64% yes, 36% no.

27. Q.—Do you go out of your way to help others? A.—21% no, 79% yes.

28. Q.—Do you favor women smoking? A.—10% no, 90% yes. Q.—Do you prefer modern women to the "old fashioned" girl? A.—88% yes, 12% no.

29. Q.—How would you rate nurses morally compared to other groups of women? A.—12% lower, 76% equal, 12% higher.

30. Q.—How do you rate male professional students morally to other groups of men? A.—9% lower, 82% equal, 9% higher.

31. Q.—Do you believe that women are the mental equals of men? A.—93% yes, 7% no.

32. Q.—Do you use alcoholic beverages frequently? A.—72% do, 28% do not. Q.—Do you condemn those who do? A.—92% no, 8% yes.

33. Q.—As companions, do you prefer those who drink or those who do not? A.—76% yes, 24% no.

34. Q.—Do you ever indulge in extramarital sexual intercourse? A.—16% do, 84% do not.

35. Q.—Do you condemn engaged couples who do? A.—58% no, 42% yes. Q.—Do you condemn others who do? A.—54% yes, 46% no.

36. Q.—Have you been in a house of prostitution more than once? A.—7% yes, 93% no.

37. Q.—Have you ever had a venereal disease? A.—Three reported yes.

38. Q.—Do you attend church regularly? A.—15% yes, 85% no. Q.—Would you be as well off if you did not? A.—64% no, 46% yes.

39. Q.—Could you do as well without church? A.—86% think they could, 14% no. Q.—Do you believe in God? A.—98% yes, 1.5% no.

40. Q.—Are you tolerant of those who do not? A.—95% yes, 5% no.

41. Q.—While attending professional school has your attitude substantially changed toward:

God? A.—Yes. Q.—Study? A.—Yes. Q.—Sex? A.—Yes.

Q.—Your profession? A.—Yes. Q.—Church? A.—Yes. Q.—The race problem? A.—Yes.

42. Q.—What could an ideal church do for you? A.—Give faith, inspiration, belief in mankind.

43. Q.—In a few words, tell what is your greatest problem. A.—Financial first, problem of adjustment to new ideals fourth, getting through school fifth, family sixth, setting up practice seventh.

Thank you! If you are interested in attending sessions of the clinics you may secure application blanks at West Side Professional Schools Y. M. C. A., 1804 West Congress Street, Chicago.

CLINIC DISCUSSIONS

Personality Clinics.—In this clinic questions 1, 4, 5, 14, 15 and 41 were discussed.

Summary of Clinic Session: Technical knowledge and pleasing personality are major requirements for the successful doctor, dentist, pharmacist and nurse. Effective personality is an absolute necessity. Persons with the highest technical knowledge are not necessarily the best but those with combined traits of personality along with technical knowledge. Personality is not a substitute for technical skill and technical skill alone cannot suffice for the lack of personality. The professional student needs technical knowledge but it is also important that he acquire that kind of personality setup which makes him effective with his fellow men. And this can come only through participation in general interest and activities.

Motivations Clinic.—In this clinic questions 1, 2, 3, 22, 24, 27, 38, 39 and 42 were discussed.

Summary: Too many students seem to have everything to live with and apparently nothing to live for. They are rich in possession and poor in purpose. Objectives that are sufficiently large to command all the power we possess for their achievement, and are good for all concerned, must be earnestly sought as the basis for a well balanced, healthy life.

Character Clinic.—In this clinic questions 8, 9, 10, 11, 18, 19, 21, 29, 30, 32 and 33 were discussed.

Summary: The basic requirement of good character is honesty. The great doctors, dentists, pharmacists and nurses have all been per-

sons of integrity. Every student should ask himself "Am I honest?" "Have I ever been found guilty of dishonest practice?" In professional practice a man is in the midst of some of the most intense social problems and he may also be tempted to engage in some of the worst practices known to society. He must be basically honest if he is to be great in his chosen profession.

Social Fitness Clinic.—In this group questions 1, 4, 5, 7, 8, 9, 12, 13, 19, 20, 25, 27, 32, 34, 37, 38 and 39 were discussed.

Summary: The social world has many elements and it is not divided into distinct economic, political and historical parts. Not only are the various social sciences closely related but it is becoming increasingly apparent that the position one takes on numerous social questions is in part determined by philosophical as well as by scientific considerations. We believe that the time has come when it may be just as important for students to know whether they believe in the philosophy of the many different forms of government current in the world as it is to

know how they are organized. In a word, the professional student becomes socially fit through his understanding of the philosophy of his profession, his government and his society as well as through his participation in the various forms of government.

Adaptability Clinic.—Here questions 5, 15, 18, 20, 21, 22, 23, 24, 31, 41 and 43 were discussed.

Summary: In the discussions of the Adaptability Clinic several conclusive points were reached; mental, emotional and physical good health must be regarded as fundamental to the enjoyment of life. Mental, emotional and physical health in an individual signifies the adjustment to living conditions. Every aspect of college life affects the student's mental, emotional, spiritual and physical state. The individual's mental, emotional and physical health program is necessarily interwoven into each day's activities. It is therefore imperative that the student plan his schedule so that these important phases of life will balance each with the other.

1804 West Congress Street.

Comments and Reviews

STUDY OF THE PATIENT AS A WHOLE AS TRAINING FOR MEDICAL PRACTICE

Abridgment of an article by Dr. G. Canby Robinson, Lecturer in Medicine, Johns Hopkins University School of Medicine, Baltimore, published in the Journal of the Association of American Medical Colleges, March 1939.

I wish to discuss the advantages of home visits by medical students as bearing especially on the study of the patient as a whole, which includes consideration of his personality, environment and social setting.

Medical practice requires an understanding of the motives and circumstances that bring the patient to the doctor. Except in cases of acute serious disease or injury, patients usually seek medical care because of social incapacity. The great bulk of illness, representing progressive disease or the processes of aging in their incipient stages, chronic infections and inflammations, and disturbances of metabolism and of bodily functions of psychogenic origin, reveals itself to the patient as an inability to carry efficiently the responsibilities of his family, of his work or of other situations he is called on to face. It is this sense of inability from which comes fear or worry, uncertainty and a feeling of insecurity. The patient is primarily concerned with being restored to his accustomed place in society whether he consciously realizes it or not. For this reason an understanding of the conditions

and obligations of the accustomed place in society to which each patient hopes to be restored is a requirement of medical practice. This concept should be appreciated by the medical student and should be incorporated into his attitude toward an understanding of medical practice early in his clinical training.

The interaction between the patient and his social setting is an important factor in the causation of illness and in its treatment, as there are specific social problems related to various types of disease which require consideration both in diagnosis and in treatment. A systematic study of an unselected series of medical patients admitted to the Johns Hopkins Dispensary has shown that in 65 per cent adverse social conditions related to their illness existed and that in 35 per cent these conditions caused emotional reactions mainly responsible for their illness. It seems clear that if medical students are to understand illness and its treatment in a broad sense they must be taught to consider the patient as a total individual. Activities in this field have recently been introduced into the curriculum of at least thirteen medical schools in this country, and various methods for their conduct have been instituted. I am convinced that these new undertakings in medical education are destined to have a useful influence on the attitude of the future doctor toward illness and on medical care in general, by developing a wider interest and a better understanding of the patient as an individual.

DETAILS OF THE PLAN

Our plan is to assign at least one patient to each third year student for study as a total individual during his work in the medical dispensary. A suitable patient is selected from the new cases assigned to each student, so that he may participate in the broader study of a patient he already knows both personally and medically. A suitable patient is one who has a more or less protracted illness, requiring treatment in the medical clinic, and who lives near the hospital so that a home visit can be made conveniently.

The patient is selected by conferring with the student and with the staff member responsible for the case, and the patient is interviewed after the clinical record has been reviewed. At this interview the patient's symptoms are reviewed and expanded. A social history is obtained, and the assets and liabilities in the circumstances of the patient's life in relation to his illness are determined. The patient is given an opportunity to relate his social and emotional disturbances, and at the same time characteristics of personality are noted. Immediately after the interview it is fully described by dictation, thereby providing a record for future study. This interview is usually conducted in an office outside the clinic, where an intimate doctor-patient relationship is easily established and the student for practical purposes is, as a rule, not present, but the record is reviewed with him shortly thereafter. Plans for a home visit with the student are made at the time of the interview.

After the study has progressed sufficiently to give an understanding of the patient as a whole, the patient is presented by the student at an informal weekly conference attended by all the students in the medical group, about twenty-five in number, and covering the whole class in three groups. The student presents the essential medical aspect of the case with the patient present, and after a brief discussion with the patient in order to bring out his personality the patient is asked to withdraw. Then his social and personal problems are described and discussed. Emphasis is placed on the relation of these problems to the patient's illness and its treatment, and consideration is given to the problems of health and hygiene which the patient may present or suggest.

These conferences are attended by the public health administrator of the district, by medical social workers and frequently by staff members of outside social agencies interested in the patient presented. A psychiatrist has attended constantly during the past two years, and visitors from the board of health, from the School of Hygiene and from other departments of the medical school have attended and participated in discussions.

There are eight conferences for each group, and it is customary to present to each group patients illustrating the social aspects of circulatory disease, pulmonary tuberculosis, psychoneuroses and syphilis, while patients with diabetes, epilepsy or other chronic diseases have been presented. Cases have also presented opportunities to discuss the relation of illness to industrial employment, the problem of permanent invalidism, the methods of utilizing the resources of various public and private health and welfare organizations, and other such topics.

BREADTH OF FIELD COVERED

The study of the patient as a whole frequently leads the student to a consideration of problems of public health and of mental hygiene, or it demonstrates the significance of adverse social conditions in the diagnosis and in the treatment of illness.

This method of treatment is neither simple nor easy. Much time and energy are required to coordinate all the human elements that are concerned with its successful conduct. These human elements consist of patients, students, doctors, medical social workers and representatives of public health and social agencies. It has not been possible to have all students make a complete study, but about 60 per cent of each class have done so.

This program of teaching has been combined with systematic studies of the social aspects of illness and with problems of treatment in conjunction with the routine medical service of the hospital staff. These activities have required the full time of a physician, a social worker and a secretary, constituting a small division of the department of medicine, in which efforts are being made to keep accurate records and to accumulate recorded experience as material for study, analysis and formulation.

Several points in this plan of teaching are advantageous in the training of the doctor. The medical student takes a broad view of at least one patient in whom his interest has already been aroused by taking the history and by making the initial examination. When the student has an opportunity to see the patient in the environment of his home, the case becomes a human as well as a medical problem. For this reason it is more deeply impressed on him and he invariably gains a lasting memory of the patient, which includes not only the individual but also the disease or disability from which he suffers. The method of teaching serves to introduce the student to phases of hygiene and public health as related to clinical medicine and to demonstrate the integration of medical practice and public health. It also serves to indicate the relation of various social agencies to medical care and the numerous factors

which may need to be coordinated in considering the total health needs of an individual. Although only relatively few topics are considered by the students, the conferencees serve to cultivate an attitude of mind and to evoke a humanitarian spirit that might otherwise be repressed during the period of early clinical training. The students have an interest in their patients as individuals and are glad to have an opportunity to give expression to this interest. This field of study gives the student the idea that there is no sharp line of demarcation between medicine, psychiatry and public health; that the psychobiologic concept of the patient is applicable in various fields of medicine, and that the study of the patient as a whole has a direct bearing on medical practice.

There is need of placing greater emphasis on the study and treatment of the patient as a whole in these days of advancing specialization.

THE PLACE OF PHYSIOLOGY IN CLINICAL TEACHING

Abstract of Mayo Foundation Lecture presented by W. H. Ogilvie, M.D., London, England, at Rochester, Minn., Oct. 18, 1937, and published in Proceedings of the Staff Meetings of the Mayo Clinic June 22, 1938.

Above all things the surgeon must be an expert in topography. His anatomic knowledge must be so detailed that no problem can find him unprepared, so thorough that it is part of his subconscious mental processes. He can acquire this knowledge only by prolonged and painstaking work. But anatomic learning, which in the early days made up the whole scientific equipment of a surgeon, is today only the beginning and foundation of his art. The surgeon who regards only structure cannot advance his subject except in technical detail or even do his day's work with intelligence and insight.

It may appear that intelligence and insight are unnecessary to a manual worker, that the limits of technique have been fully explored and that nothing remains but to repeat those procedures that have already been perfected. Yet it does not follow, because no striking innovations are to be expected, that further advance is unlikely. It is impossible to visit several centers in succession, as I am doing at present, without being astonished at the great divergence in the methods used by surgeons of ability to treat the same disease. Which is right? Surgery is not complete until we can give the answer to this question, and we can only do so by applying the test of function. We must turn to physiology, the province of which is the study of function.

Physiology inquires how the viscera are normally kept in position, how this normal mechanism has failed in visceroptosis, how far the

symptoms are due to altered position, and how the normal function and support can be restored. The viscera are kept in shape by the tone of their own walls and in position by the tone of the abdominal muscles and pelvic floor. Failure is due to lack of tone, and tone in turn is dependent on influences from higher centers, and ultimately on psychologic control. The treatment of visceroptosis is therefore the restoration of tone, psychologic tone, tone of the abdominal muscles and tone of the visceral walls.

I may choose the muscular system to illustrate the tendency toward departmental knowledge. In anatomy we learn the attachments and nerve supply of each voluntary muscle and regard its actions as a piece of elastic. In physiology we study the behavior of nerve muscle preparations from the frog and pass on to the more general characters of the activity of striated and plain muscle. In clinical surgery we think of muscles chiefly as things that may be injured or that interpose barriers to structures we wish to reach. We seldom pause, except in orthopedics, to consider them as the chief constituents of the human body or to apply that knowledge of the living muscular system as a coordinate whole. This idea we owe, in the main, to the work of Sherrington. This knowledge does, however, color orthopedic teaching and practice at present. We are taught to recognize two types of activity, the phasic and the tonic. We know that a muscle may be strong in the phasic sense yet grossly deficient in tone. As surgeons we should be alive to the need of preserving abdominal tone which is lost after abdominal operation.

We cannot go through the abdominal muscles by peaceful penetration. We must cut them. We should so plan our incisions that they do no permanent harm and interfere as little as possible during the process of healing with abdominal movements, and we should so close them that the muscles may be used from the start without risk of damage. A perfect incision would divide all structures along their lines of stress, so that contraction tends to approximate rather than to separate them and the stitches do no more than obliterate dead space. Thus the gridiron is the only incision against which no criticism can be directed. For any but small operations, however, we must divide the rectus sheath although we should hesitate to cut the muscle itself. Such a wound, well healed, leaves the abdominal wall undamaged.

It is of little avail if we enable our patient to use his abdominal wall but do not allow him to do so. As a physiologic mechanism the abdominal wall demands activity. A well sutured wound has a tensile strength of about 40 per cent of that of the tissues before they were cut. During the first few days the tissues

undergo autolysis while the sutures are being digested. By the fourth day the strength of the wound has sunk to some 20 to 25 per cent of the original. From the fifth day onward fibroblasts are laid down rapidly and the strength increases, so that by the sixth day it is 50 per cent and by the tenth day about 90 per cent of the normal. It appears, therefore, that wound rupture is most to be feared between the third and the fifth day, and after that it becomes increasingly unlikely. But while repair requires rest it is not necessary to rest the whole muscular system, or even the whole abdominal wall, nor need rest mean rest in one position. Let us set our faces against the routine use of the encircling bandage and the Fowler position. As soon as the chart indicates a reestablished circulation and freedom from chest trouble, it is unnecessary to prescribe any particular position. The patient may be allowed to lie on his back, his side, his face or curled up, as previous habits dictate and present comfort allows. His protective reflexes will guard the wound from undue strain. But to allow or force him to walk before the tenth day is to permit physiologic idealism to override pathologic common sense.

Before I leave the topic of the abdominal wall I would touch on the layer that most concerns the patient, the surface one. The skin has many metabolic functions, but I shall think of it now only as a flexible and almost indestructible cover, yielding to all movements of the body without pain and without tension. We must traverse the skin to reach the underlying parts, but the less trace we leave of our passage, the less shall we interfere with its free movements afterward. Cosmetic surgery may seem to be far from physiology and entirely out of place in the abdomen, but a beautiful scar is more than a work of art: it is an indication of healing not merely by first intention, but without any recognizable reaction of repair it means that any subsequent operation will find tissues in appearance and texture equal to normal. We can have scarless surgery only by operating where there is a scar already. Creases are scars, that is they are fibrous intersections passing from the skin through superficial fascia to the aponeurosis below. They are fixed because they lie in a plane of no movement, and an incision placed along them will not merely heal beautifully because it remains approximated with the aid of stitches but it will not subsequently interfere with or limit movement.

My theme, in short, is to suggest that we may occasionally turn the torch of inquiry backward as well as forward, look for that which has been forgotten as well as that which has not yet been discovered, and try to piece the work of others into our daily task.

THE MEDICAL RACE

Abstract of an inaugural address delivered by Robert Hutchison, M.D., D.Sc., LL.D., at the opening of the session of the Westminster Hospital Medical School, October 3, and published in the Lancet Oct. 8, 1938.

I wish today to give you some advice on how to run the medical race. I have been over the course and can perhaps warn you of some of its difficulties. I should like to congratulate you. I would commend it on the grounds that medicine is an interesting, intriguing and even amusing occupation in which, although with all its labors and langors you may often know fatigue, you will at least escape boredom; that it gives opportunity for the exercise of your physical, mental and moral powers and that it offers an admirable field for the study of human nature in the raw. It is customary to say that although it is easy enough to earn a living in medicine it is difficult to make a fortune in it. But in no learned profession is it easy to make a fortune, and on the whole doctors are quite well paid and they have this further advantage that their skill, once acquired, is marketable all over the globe, for disease is everywhere the same.

THE NUMBER OF COMPETITORS

Today's ceremony corresponds for many of you to the fall of the flag starting you off. Some of you may be feeling a little dismayed by the large number of competitors. I was half a century ago, for there were more than 400 men in my year at Edinburgh. I advise you not to be discouraged. The saturation point does not seem even yet to have been reached and the scope and amount of medical work are always increasing. As Dean Inge, I think, has said, though Democracy may starve the clergy and the practitioners of the arts, it will always demand doctors.

THE HURDLES

I want to remind you that this race is a handicap race; you don't all start level. Nor is there any use in pretending that the handicapping is fair. Some of you will carry weight all through the course because of poor health, lack of intelligence, inborn laziness, shyness or a bad manner. Others may be burdened by poverty if that is really a handicap. Rightly regarded it may be a spur; indeed it might be said that the rich parent can give his son every advantage except poverty. A few of you may handicap yourselves by habitual idleness or by the acquisition of vices or debts.

The race is not really very long. Eight laps of five years each will see the end of it for most of you; and although forty years may seem a long time to look forward to it is surprising how short it is in retrospect. The first lap, as many of you have already realized, is a hurdle race, the hurdles being the examinations. I refuse to diverge into a discussion of medical education,

which will still be under consideration when the day of judgment arrives, but, in the last resort each of you will have to train himself. If I have any guiding principle in teaching the medical art it might be summed up in the saying You must get as early into contact with patients as you can. We will suppose you then to have completed the first lap. You are now out of the hands of your trainers and in open country where the race becomes a point-to-point and each can choose his own line, and here you may go astray in various ways.

You may run up a blind alley. There are many of these opening out of the course and some of them look attractive; so-called research posts of one kind or another and small institutional jobs are amongst them. Beware of these; they offer an immediate reward in pay but are apt to lead nowhere. Above all, shun research posts—the “lure of the laboratory”—unless you feel in yourself the curiosity and restlessness of the born investigator.

Second, you may be tempted out of your course by the desire to make a good income quickly. This is the bait which may draw you down one of those blind alleys; but even if it does not do that it may result in your starting on a definite path when, if you had taken time to study the country properly, you might have found another that would have suited you far better. I don't like to make generalizations about the rising generation, but I think that the newly qualified man is more mercenary in his outlook now than he used to be.

The third danger against which I would warn you at this point is the premature engagement; indeed, it may easily be the cause of your running into either of the two false courses to which I have already referred. Don't make a three-legged race of it too soon. I know the sentimental reasons in favor of doing so—the “stimulus of having some one to work for” and so on. I remember too the advice of the old lady: “Young man, don't be a doctor. You can't marry till you get a practice and you can't get a practice till you are married.” It remains true that at this stage of the race “he travels the fastest who travels alone.” When Eros calls, you are not likely to remember this advice; but, as Sir William Osler used to say, “You must learn to keep your emotions in cold storage.”

CHOICE OF A LINE

Having escaped these hazards, you have to choose your line of country. I would advise you not to decide hastily but to have a good look round first and get as much general experience as you can by doing resident appointments. On the other hand, it is unwise to hold such posts too long; sooner or later you must strike out on your own. Don't become an appointments addict.

There are plenty of lines to choose from, for in the house of Medicine are many mansions; but I suppose the majority of you will find yourselves in general practice. I am not going to throw boquets at the general practitioner, for he needs no praise of mine. It is customary to describe him as “the backbone of the profession,” but I prefer to regard him as the soldier in the front line of the medical army who has to withstand, often single handed, the first assault of disease. He is all the more to be envied on that account. A man in a good country practice particularly is a real doctor, not a mere sorting machine for consultants or hospitals, and is probably living as full, useful and happy a life as our profession offers.

I may warn you of another danger in the race. Those of you who have read the Pilgrim's Progress may remember that at one point Christian was joined by two men, Formalist and Hypocrisy, who got into the way of climbing over the wall instead of entering by the gate, and you will find in the race of practice that some persons get on to the course without having first jumped the hurdles. We call these quacks and, like the two men of Bunyan's vision, they come from the land of Vainglory and we may say to them, as Christian said to Formalist and Hypocrisy, “You walk by the rude working of your fancies.” I should advise you not to regard them as real competitors and above all never to imitate their methods of running. They may beat you sometimes in treatment, for patients still like magic, but in matters of diagnosis you will always leave them standing.

THE MEANING OF SUCCESS

If you ask what makes for success in the race of practice I cannot tell you. It is not knowledge or manners, for a doctor may achieve a large practice without either of these. The power of inspiring confidence is possibly the one thing needful, but I really don't know. Everything depends on what one means by success. Some estimate it in terms of money and it is foolish to say that this does not count; some think of honors of one sort or another, but these are of little value unless bestowed by one's fellow competitors. Let us agree that so far as practice is concerned that man has succeeded who has gained both the affection of his patients and the esteem of his colleagues.

When all is said and done, ours is a race in which there are many kinds of success and no one winner. Perhaps it is not so much where you come in as how you ran that matters.

They win who never near the goal,
They run who halt on maimed feet,
Art has its martyrs like the soul—
Its victors in defeat.

And that is true of the art of medicine.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Annual Meeting of Association of Medical Students

The fourth annual meeting of the Association of Medical Students will be held at the Detroit-Leland Hotel, Detroit, December 22-29. Among the speakers will be Drs. Morris Fishbein, Chicago, Editor of *THE JOURNAL*; George W. Crile, Cleveland; Walter C. Alvarez, Rochester, Minn., and Frederick A. Coller, Ann Arbor, Mich. The registration fee, including luncheon, dinner, dance and two or three nights at the hotel, will be \$8.50; the fee is \$3.50 for those not staying at the hotel. At a meeting of the National Executive Committee of the Association of Medical Students, New York City, July 3-5, it was decided that chapter delegates to the national conventions shall be elected on the basis of one for every twenty paid-up members as of December 1. Each delegate shall be entitled to one vote.

Prizes to Encourage Writing

The University of Indiana School of Medicine, Indianapolis, announces that Mr. H. Osterman, of Seymour, Ind., has offered annual prizes for outstanding papers by students in the medical school. There will be three prizes of \$30, \$25 and \$25 for case reports; three prizes of the same amounts for statistical studies, and two prizes of \$25 and \$15 for outstanding papers. The judges for the selection of the winners comprise the editors of the *Bulletin of Indiana University Medical Center*: Drs. Jacob K. Berman, Willis D. Gatch, Robert L. Glass, Harold M. Trusler, Ernest Rupel, Edgar F. Kiser and Frederick W. Taylor.

One in Ten Applicants Accepted at Temple

The thirty-eighth session of Temple University School of Medicine, Philadelphia, opened September 20 with the following enrolment: freshmen, 110; sophomores, 98; juniors, 118; seniors, 119. The total of 445 includes 127 students enrolled for the first time. These students completed their premedical courses in sixty-seven colleges. The states represented are California, Connecticut, Delaware, Florida, Idaho, Michigan, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Dakota, Utah, Washington and West Virginia; Puerto Rico is also represented. There are seventy-two Pennsylvanians, twenty-three sons and daughters of physicians and also six women students. The freshman class was selected from a total of 1,196 applicants who submitted formal applications and credentials.

Student Opinion Surveys

For more than two years Student Opinion Surveys of America, with headquarters at the University of Texas, has been conducting research on public opinion among the college students of America. Personal interviews are used to gather opinions at regular intervals in colleges throughout the United States, and the ballots are then mailed to Austin, Texas, for national tabulation. This is the only such college poll, it is said, that uses personal interviews to gather opinions. In this way a cross section is established, and the opinions of the million and a half college students are measured accurately. The project is concerned only with disclosing facts about student sentiment and does not seek to influence public opinion. Pressure groups or student movements have no part in the surveys. Ballots are carefully distributed according to

geographic sections, sex, age, class in college, political affiliation, whether the student works or not, and type of school. Among college papers which will published these polls is *The Tiger*, Journal of Tulane University of Louisiana School of Medicine, where the personal interviews will be conducted by Malter Salatch, member of *The Tiger* staff, with Spurgeon M. Wingo editor of *The Tiger* acting as local director of the polls.

Fellowships at Washington University School of Medicine

Students at Washington University School of Medicine, St. Louis, in the upper three classes of the school who are deserving on the basis of need, scholarship and character may obtain loans granted by the chancellor on recommendation of the Committee on Loans and Scholarships and the dean. For example, under the will of the late Jackson Johnson, \$250,000 was donated to the university, the income from which is used to aid worthy and desirable students in acquiring a medical education. From this fund honor scholarships are provided to exceptional students who are applicants for the first year class, each scholarship carrying an annual stipend of at least \$300 and not more than \$1,000. The Eliza McMillan Student Aid Fund comprises the annual income from \$7,000, which may be awarded to a deserving woman student in the school of medicine. The T. Griswold Comstock scholarships comprise the annual income from \$12,000, which is used for two scholarships for students who otherwise would be unable to obtain a medical education. There is also the Alumni Scholarship Award of \$100 to be applied on payment of tuition fee, given for excellence in work during the preceding scholastic year. Application for all these awards and aids should be made to the dean of the medical school.

The Medical Son of an American Physician in Argentina

The son of an American doctor occupies a very high place in the memories of Argentine physicians. Dr. Aman Rawson, a United States Navy physician, on his third trip to South America decided to settle in the Plata region in 1818, the year when San Martin's victory at Maipu secured its independence from Spain. Dr. Rawson's son, Guillermo (William), was named after the Philadelphia colleague who had induced the father to go to Argentina. Guillermo Rawson was renowned not only as a physician but also as a statesman. It has been said that he was too valuable in politics to be allowed to be buried in his profession. Rawson's versatile personality and achievements have recently been sketched (Araoz Alfaro, G.: *Cronicas y Estampas del Pasado*, 1938; Un Vastago Norteamericano en la Republica Argentina: Guillermo Rawson, 1939). Memorials have been raised to him in Buenos Aires. He was the first professor of public health in Argentina and his classes were the most popular in the school. He submitted to the international congress in Philadelphia in 1876 the first study of the vital statistics of Buenos Aires. In 1854 he foresaw aerial navigation by machines heavier than air. Rawson, as a member of the cabinet, signed the contract for the first cross country railroad in Argentina (1864), drew the bill for the creation of a department of agriculture and put through congress the law on a national census. One of Rawson's most noted characteristics was his devotion to the country of his parents. No occasion was neglected by him to

bring American principles to the attention of Iris countrymen. One of his books deals with American politics. His standards were high; not even a bid to the presidency could make him change his stand. At his death a state funeral was decreed, and former President Mitre truly said that never had he known a man more closely approaching moral perfection.

Dr. Cannon Addresses North Dakota Students

Dr. Walter B. Cannon, Boston, gave three addresses to the students of the University of North Dakota School of Medicine, Grand Forks, October 11. His subjects were "Chemical Mediation of Nerve Impulses," "Maintenance of Bodily States" and "Effects of Strong Emotions." The lectures were arranged through the cooperation of the medical school, the Grand Forks District Medical Society and Sigma Xi.

Loans to Students at Medical College of Virginia

The Medical College of Virginia, Richmond, has certain funds from which limited amounts may be loaned to assist worthy medical students in the pursuit of their studies. Small amounts are available from the William Karp Memorial Loan Fund and the Lewis Z. Morris Memorial Fund. The Student Body Loan Fund was appropriated from unexpended balances from organized student activities for the purpose of making loans to students through a committee of the student body and the secretary-treasurer of the college. There is the Benjamin Hobson Frayser Loan Fund, the General Loan Fund and the State Loan Fund, the last derived from an appropriation by the state of Virginia of \$1,000 annually for loans to Virginia students of ability and character who are in financial need. The amount lent in any one session from the State Loan Fund to students of medicine is limited to \$137.50. Preference will be given to applicants who have completed the first year course.

Fees at the Medical College of Virginia

The tuition for medical students at the Medical College of Virginia, Richmond, is \$275 for Virginia students and \$400 for non-Virginians. There is a matriculation fee of \$10, as well as laboratory fees in the first and second years of \$15, a contingent deposit of \$20, student health service \$12, student activities \$12 and certain few other fees connected with graduation.

Senior medical students at this school, unless residents of Richmond or excused for special reasons, are required to live and board at Hunton Hall, in which the rate for the session, payable one half at the beginning of each semester, is \$150 for single rooms; \$130 per student for double rooms, with board at \$22 a month. The rate for board is subject to change without notice. Suitable board and room may be obtained in the city of Richmond from \$30 to \$35 a month.

After the first year in the school of medicine it is often possible for a student to find outside employment to help pay expenses. There are junior internships and other hospital positions, for example. Students are not encouraged to seek employment which requires any appreciable amount of time, as it frequently leads to failure in college work.

Student Organization at Western Reserve

The student body at Western Reserve University School of Medicine, Cleveland, has organized the Student Cooperative Association for the cooperative purchase of instruments, books and other supplies, from

which each member receives a pro rata dividend at the end of the school year. A member is charged a small membership fee. The association is under the control of a board of student directors.

Aid to Students at Western Reserve

Western Reserve University School of Medicine, Cleveland, has available certain funds from which limited loans to promising and needy students can be made. These funds are provided by the Medical Alumni Association, the Student Aid Fund and the Biggar estate. During the last school year, twenty-five students received fellowships, scholarships or loans. The medical school feels that it is impossible for medical students to undertake any other work during the school term without serious and perhaps fatal detriment to their medical studies. However, the school will endeavor to assist students to obtain suitable employment should this become absolutely necessary. In such cases the student should first consult the class adviser. The total necessary expenses at the school for thirty-four weeks, including books, instruments, board and room, but exclusive of tuition and fees, according to the *Western Reserve University Bulletin*, need not exceed \$800.

Loans for Women Students

A trust fund of \$5,000 was established years ago in the Woman's Medical College of Pennsylvania, Philadelphia, by Elizabeth H. Francis for the purpose of assisting needy students, for which loans interest is charged at such a rate as the committee may decide. These loans are secured by an endorsed note, a life insurance policy or such other security as shall be acceptable to the board of corporators. Repayment in instalments begin not later than three years from the date of graduation and must be completed within seven years from that date.

Other means of assisting students are available, including awards of scholarships and other loan funds.

Expenses of Woman's Medical College

The Bulletin of the Woman's Medical College of Pennsylvania, Philadelphia, estimates that the expenses for the first year in the medical school are as follows:

Matriculation fee.....	\$ 5.00
General tuition fee (admitting student to all lectures and laboratory courses belonging to the year)....	400.00
Library fee.....	2.00
Credential fee.....	2.00
Medical service fee (entitling student to x-ray examination of chest, which is required on admission, to advice at the daily student dispensary hour and to emergency care at her room by the student physician; it does not entitle the student to free care in the hospital).....	8.00
Materials fee.....	15.00
Breakage deposit.....	8.00
Locker charge.....	.50

Getting Acquainted at Tufts College

At Tufts College Medical School, Boston, there is, a unique method of achieving a desirable student-faculty relationship. Five of the faculty members and the dean, representing such diverse groups as the Committee on Admissions and the Alumni Council, constitute the Student Relations Committee, the chairman of which, Dr. Benjamin Spector, professor of anatomy, is the first member of the faculty to come in contact with the new class. During the first few weeks of the year Dr. Spector prefaces his lectures on anatomy with the introduction of some member of the faculty, who talks briefly to the new students. After a number of the faculty have in this fashion become known to the new students, the entire faculty holds a reception

for first year men and women. The Student Relations Committee assists at this reception by rotating the individual faculty members among the students from group to group while a buffet supper is served. Informality is the keynote. Following the supper, the president, the dean and others give brief words of greeting. This procedure has been employed for several years with much success.

Long Island College of Medicine

The Student Council at the Long Island College of Medicine, Brooklyn, is conducting a survey of the economic status of the students to determine what percentage of them must earn tuition, room and board, and how much assistance they receive from other sources. Bob Hughes is directing the study for the Student Council. Should the results of the survey warrant, the Student Council may suggest that an employment bureau be established at the college. Last summer the majority of the present senior class served junior internships; six members of the class, however, worked on a statistical project in venereal diseases being conducted by the U. S. Public Health Service. Each one of these six students, among other things, had to read many hundred of venereal disease case histories. The present freshman class at the college has ninety-nine members, graduates of forty-three colleges and universities. The school year opened September 25 with a formal ceremony in the amphitheater at Polhemus. At the last commencement the address was delivered by Dr. Charles Gordon, professor of clinical obstetrics and gynecology, and director of the teaching division of that department at the Kings County Hospital, Brooklyn.

History of Medicine for Freshmen

The series of lectures on medical history announced for the freshman class at Tulane University of Louisiana School of Medicine, New Orleans, was initiated October 4 by a lecture on the "History of Tulane" by the dean, Dr. C. C. Bass, and followed October 25 by a lecture on the "History of Anatomy" by Dr. B. Bernard Weinstein. Other lectures have been scheduled in this series as follows: "Development of Microscopic Anatomy," Harold Cummins, Ph.D., November 15; "History of Physiology," Hymen S. Mayerson, Ph.D., November 29; "History of Physiology," Dr. Mayerson, December 6; "Development of Biochemistry," Sidney B. Bliss, Ph.D., December 13: Dates are to be assigned for the following lectures: "History of Pathology," Dr. Charles W. Duval; "History of Parasitology," Ernest C. Faust, Ph.D.; "Landmarks in Medicine," Dr. John H. Musser; "The Instrumental Aids in Medicine," Dr. Roy H. Turner; "The Rise of Hospital and Public Health Service," Dr. William H. Perkins; "The Development of Psychiatry," Dr. Theodore A. Watters; "The Development of Pharmacology," Dr. Erwin E. Nelson; "Medical Bibliography and the Use of the Library," Mary L. Hutton.

Scholarships at Maryland

Among the scholarships available at the School of Medicine of the University of Maryland are the Dr. Samuel Leon Frank Scholarship (\$100)—no student may hold this scholarship for more than two years; the two Charles M. Hitchcock Scholarships (\$100 each); the Randolph Winslow Scholarship (\$100), awarded annually to a needy student of the senior, junior or sophomore class, who must have maintained an average grade of 85 per cent in all his work; the Dr. Leo Karlinsky Memorial Scholarship (\$125); the University Scholarship, which entitles the holder to exemption from payment of tuition fee for the year, awarded to a senior student in need of assistance;

the Frederica Gehrmann Scholarship (\$200), awarded to a third year student who has passed the best practical examinations in certain subjects; the five Clarence and Generva Warfield Scholarships (\$300 each), available to students of any of the classes, but a recipient must, after graduation and a year's internship, practice for two years in the county of Maryland to which the student is accredited or in a county selected by the medical council; the Israel and Cecilia E. Cohen Scholarship (\$150), a recipient being obliged after graduation and a year's internship to practice for two years in the county to which he is accredited; and the Dr. Horace Bruce Hetrick Scholarship (\$125) awarded by the Medical Council to a student of the senior class.

Personal Expenses at Maryland

Estimates of a student's personal expenses in Baltimore for the academic year of eight months at the School of Medicine of the University of Maryland have been prepared by students based on actual experience. The following estimates appear in the latest available bulletin of the school; there is in addition a certain expenditure for a microscope:

Items	Low	Average	Liberal
Books	\$ 50	\$ 75	\$100
College incidentals.....	20	20	20
Board, eight months.....	200	250	275
Room rent.....	64	80	100
Clothing and laundry.....	50	80	150
All other expenses.....	25	50	75
Total.....	\$409	\$556	\$720

Aid for Students at Nebraska

Scholarships are available in the various departments of the University of Nebraska College of Medicine, Omaha, in return for student assistance; applications should be made to the chairmen of the various departments. In addition, there is available the income from the Jetur Riggs Conkling and Jennie Hanscom Conkling Foundation, which is to be used in providing scholarship loans for deserving medical students, awarded only after the close of the first year in medical college, and the scholarship loans are not to exceed \$200 a year; the Omaha Medical College Foundation Fund of more than \$15,000, the income from which is available to worthy students. Students should make a written application for benefits under this fund to the dean of the medical school. The Nebraska Federation of Women's Clubs makes an annual grant of \$200 to a student in the college of medicine on the basis of scholarship and financial need.

Student Society at Pittsburgh

The Students' Medical Society of the University of Pittsburgh School of Medicine holds quarterly scientific meetings at the Pittsburgh Academy of Medicine, where papers written by medical students are read. The society also sponsors an annual reception for the freshman class, the medical school year book and a student loan fund.

Expenses at Nebraska

According to the *Bulletin of the University of Nebraska College of Medicine*, the expenses at this school are estimated in part as follows:

Board may be obtained in the vicinity of the college campus at an average of \$8 a week. Comfortable rooms for individuals cost from \$10 to \$15 a month. Students rooming together may obtain comfortable rooming quarters at approximately \$8 a month each. The average expense of the student for a school year, including books, instruments and all fees, is between \$700 and \$900. Students should provide an allowance of \$75 a year for books and instruments.

Loan Funds at University of Illinois

The University of Illinois College of Medicine, Chicago, has available a number of loan funds for the benefit of worthy students who are in need of financial aid in order to finish their courses at the school. Applicants should apply to the dean's office for detailed information.

Students having the following undergraduate scholarships at this school are exempt from matriculation and tuition fees but are required to pay all laboratory and dispensary fees:

General Assembly Scholarships—One nomination each year by each member of the general assembly. Nomination must be received by the president of the university not later than the first Monday in July.

State Military Scholarships—for World War Veterans. Special provisions were passed by the General Assembly in 1919. Address the registrar of the University of Illinois at Urbana for detailed information about these scholarships.

Additional scholarships include the following:

Four Rea scholarships. These are awarded each year by officers of the faculty for worthy students. These scholarships last year were granted to Henry S. Bernet, Glenn A. Hoss, Leland J. Mortenson and LeRoy E. Walter.

The Charles Spencer Williamson Memorial Scholarship. This is awarded annually to a capable and needy student either graduate or undergraduate, the award to be made by the dean and head of the department of medicine. Last year this scholarship was awarded to Harve W. Jourdan Jr.

The Theodore B. Schnitzer Memorial Scholarship. This scholarship of \$100 annually is available to a needy Jewish student who ranks in the upper half of his class and has completed at least one year in the college of medicine. This scholarship is awarded by a committee of the faculty and in 1938 was awarded to Milton Feinberg.

The late Dr. Frank Smithies endowed an annual prize in memory of William Beaumont, which is awarded by a committee to the student or faculty member who submits the best original work on diseases of the alimentary tract. In 1938 the twelfth award was made to Dr. Alexander J. Nedzel.

A \$100 prize is given every other year for the best contribution in the field of allergy by any student or member of the faculty of the college of medicine. This prize will be awarded in 1939.

The annual Sigma Xi prize of \$25 for the best scientific investigation by any student in the college of medicine, the college of dentistry or the graduate school was awarded last year to Milton Engel and Philip Wesoke for their paper entitled "A Cephalometric Appraisal of Congenital Hypothyroidism."

Georgia

A chapter of Alpha Omega Alpha, honorary medical society, has been installed at Emory University School of Medicine, Atlanta. Dr. Walter L. Bierring, Commissioner of Health of Iowa and national president of the fraternity, was present and conferred the charter of Beta chapter of Georgia. The student initiates who were chapter members were Frederick W. Cooper, Talbert Cooper, Cecil B. Elliott, John P. Gifford, John R. McCain and John H. Ridley.

Fees at Stanford University School of Medicine

The tuition fee for students in the school of medicine is \$115 a quarter. A deposit of \$20 is required of each applicant admitted to the entering class or to advanced standing in the school of medicine within ten days after receiving notice of his selection, this deposit being applied on the payment of his medical fees for the first quarter.

The community fee for all students, except those registered at San Francisco, is \$15 a quarter. This fee covers the privilege of the gymnasiums, athletic grounds, the Hospital Fund, the Stanford Union or Women's Clubhouse, the Memorial Hall Fund, and

membership in the Associated Students. All students registered in San Francisco are charged a student health fee of \$5 a quarter, a fee of \$1 for student athletic privileges and, during the winter quarter, a student body fee of \$1.

A general library fee of fifty cents a quarter is charged each undergraduate and graduate student registered in the university except students in the school of medicine in San Francisco and students registered in professional schools collecting their own library fees.

In addition, students are charged for the materials which they use. They also may be required by any department to make a deposit to cover breakage or loss of apparatus and materials, such deposits being returnable, less charge for breakage, loss or wear and tear of apparatus. The total deposits for this purpose may vary from \$10 to \$20 a quarter.

Drafts and checks should be drawn for the exact amount to the order of Stanford University School of Medicine, as no change can be returned to students on checks or drafts.

Aid to Students at Stanford

Among the scholarships, loan funds and fellowships available to medical students at Stanford University are the Florence Hecht Fries scholarship in medicine, the income from a fund of \$5,000 awarded annually to a needy student; the Carrie Hassler Scholarship, the income from a fund of \$6,300 awarded annually; the Agnes Walker Scholarship, the income from \$12,000 awarded annually to a woman medical student; the Alpha Omega Alpha Loan Fund administered by the dean of the school of medicine; the Alumni Jordan Medical Scholarship Loan Fund, for the purpose of paying the tuition fees of several medical students of high standing with the stipulation that at some future time the amount will be returned; the Dr. Robert Patek Memorial Loan Fund to assist medical students in completing their courses. The loans bear no interest until one year after graduation and then bear 6 per cent interest until paid; the Stanford Medical Alumni Revolving Loan Fund, restricted to medical students in San Francisco (loans are limited to \$50 at any one time); the Romaine Josephine Stanley Fund; the Dr. Phil H. Weber Fund for deserving students, the loans bearing 6 per cent interest annually until paid; the Women's Auxiliary of the Alameda County Medical Association Fund, lending \$100 to a third or fourth year student whose home is in Alameda County, and the Jane Darling Stevenson Memorial Fund, the loans being restricted to women medical students in the advanced classes. This particular fund is administered by the chairman of the National Committee of Alpha Epsilon Iota, Dr. Monica Donovan, suite 1839, 450 Sutter Street, San Francisco. Information concerning the other funds mentioned may be had from the dean, Stanford University School of Medicine, San Francisco.

Wisconsin State Board Questions

The following questions in roentgenology were given at the examination held in Milwaukee June 27-30, 1939, by the Wisconsin State Board of Medical Examiners:

1. What are the characteristics of a fracture line?
2. What are the x-ray characteristics of a pyogenic process?
3. What are the commonest x-ray characteristics of syphilis of the bone?
4. Does hyperpituitarism produce any bone changes?
5. How would you differentiate gallstones from kidney stones?

All questions were to be answered.

ACUTE PERFORATION OF PEPTIC ULCER

IMMEDIATE AND LATE RESULTS IN
FIVE HUNDRED CASES

HAROLD LINCOLN THOMPSON, M.D., Ph.D.
LOS ANGELES

In the treatment of acute perforation of peptic ulcer neither the immediate nor the late results are wholly satisfactory. Immediate mortality is distressing and subsequent morbidity often embarrassing. Yet, considering the percentage of deaths when the condition is neglected, one is heartened by the fact that a majority of lives are saved by surgical treatment.

Immediate mortality in peptic ulcer complicated by acute perforation is dependent on many factors. The more important factors are not always under the control of the surgeon. Subsequent morbidity follows perforation largely because in most instances the risk to life is such as to prevent the surgeon's doing anything toward the cure of ulcer at the time of operation. Obviously if improvement in immediate and late results is to be obtained it must be accomplished through better control of the factors which affect morbidity and mortality. As surgeons, we must accept the challenge from the manifest need for improvement in end results.

LITERATURE

The literature on immediate results concerns itself chiefly with mortality and early symptomatic relief. The literature on late results revolves around the permanency of symptomatic relief and the further medical or surgical requirements of the patient. Published figures on mortality range all the way from 0 to 85.7 per cent, depending somewhat on the size of the series under discussion. For example, among Eliason and Ebeling's¹ collected cases there are seven reported series consisting of from six to twenty-two cases each in which there was no mortality. However, in eighteen series each consisting of 100 or more cases the mortality ranged from 12.9 to 38.8 per cent.

In 1908 Moynihan,² a pioneer in gastric surgery, reported a series of twenty-seven operations for perforation in which the mortality was 34 per cent. By 1928 his series had grown to 237 cases wherein the average mortality was 25 per cent. In Eliason and Ebeling's collected American series of 1,940 cases the mortality was 25.9 per cent, whereas in their European

series of 3,121 cases the mortality was 22.6 per cent. The average mortality in 5,061 collected cases, therefore, was 23.9 per cent.

Other factors which play a part in mortality are the interval between perforation and operation and the type of operation performed. Storey³ in 1936 reviewed a series of 261 cases in which the mortality ranged from 6.1 to 85.7 per cent, depending on the interval between perforation and operation. In a similar report by McCreery⁴ in 1938 the mortality ranged from 4.3 to 80 per cent.

In 1924 Bundschuh⁵ reported a small series of cases wherein mortality following conservative surgical treatment was 62.5 per cent whereas following radical pyloric resection it was only 16.6 per cent. Yudin⁶ in 1937 reported 331 Billroth I and Polya pyloric resections with the remarkably low mortality of 7.8 per cent. In 1937 Shawan⁷ reviewed 356 cases from the Detroit Receiving Hospital wherein the mortality ranged from 9.5 to 50 per cent with active treatment, depending on the type of operation employed.

Lewisohn⁸ in 1928 reported failure to cure in 39 per cent of cases, and in 1929 Olson and Cable⁹ found persistent symptoms in 10 to 67 per cent of cases, depending on the type of operation performed.

In 1932, Shelley¹⁰ reported follow-up analysis of fifty-nine cases traced for from one to five years and found 67 per cent cures.

PRESENT SERIES OF CASES

This report is based on an analysis of 500 cases of acute perforation of peptic ulcer collected from the charity services of Los Angeles hospitals between Sept. 9, 1921, and June 30, 1934. Except for 1.8 per cent of cases in which the clinical diagnosis was correct beyond doubt, all the perforations were proved by operation or autopsy. This requirement of proof automatically excluded many cases in which the condition was clinically diagnosed and medically treated, especially those in which recovery took place. The mortality figures are affected accordingly.

Operations were performed by fifty-seven surgeons, with an average of 8.7 cases each. Such factors as site of perforation,¹¹ causes of death¹² and other clinical features¹³ of the present series of cases are reported elsewhere.

IMMEDIATE RESULTS

Clinical Results.—According to the hospital records 206, or 41.2 per cent, of the patients were followed for periods ranging from a few weeks up to eighteen months (fig. 1). Among them 125, or 60.6 per cent, obtained complete relief after operation, whereas sixty-five, or 31.5 per cent, required medical treatment and sixteen, or 7.7 per cent, required further surgical treatment, as

Fig. 1.—Immediate clinical results.

shown in the accompanying table. In seven cases, or 3.3 per cent, reoperation of peptic ulcer occurred, whereas in twelve, or 5.8 per cent, massive hemorrhage took place.

Of the cases in which further surgical treatment was required, gastrojejunostomy for obstruction was performed in eight, simple closure of reoperation and pylorotomy each were performed in two, whereas exploration, jejunostomy, pyloroplasty and sleeve resection were performed in one case each.

Gastrojejunal ulcer occurred in two of the cases in which gastrojejunostomy had been performed.

Gross Mortality.—Gross mortality, the mortality irrespective of the type, promptness or lack of treatment, includes the entire group of 500 cases (fig. 2). In this series 197 patients died, representing a gross mortality of 39.4 per cent. In 60.6 per cent of cases recovery took place.

Type of Treatment.—In seventy-six cases nonsurgical or expectant treatment was used (fig. 3). In this group there was only one recovery, which represents a mortality of 98.6 per cent. In 424 cases surgical treatment was used, with a mortality of 28.7 per cent. It is to be noted that between the two types of treatment the spread in mortality amounts to 70 per cent.

Interval.—The interval between perforation and operation long has been known as one of the most important factors which concern mortality and one which it is possible for the surgeon to control in only a portion of the cases. Generally it is taught that the mortality is directly proportional to the interval. That this is not always the case is shown by this study (fig. 4).

The cases are divided into four groups. In the first group the perforation had existed six hours or less; in the second, for seven to twelve hours; in the third, thirteen to twenty-four hours, and in the fourth, twenty-four hours or more. The first two groups comprise 130 and 168 cases, respectively. It is of interest to note that the figures for mortality in these two groups are within 0.5 per cent of each other, being 21.5 and 22 per cent, respectively.

Comparing the third group with the second, one finds a sharp rise in mortality to more than double when operation is delayed until the second twelve hour period. On the other hand, in the fourth group there is a reduction of mortality by 12 per cent among those whose operation was delayed for twenty-four hours or more. In view of the extremely high mortality in patients treated expectantly, I am sure no one would wait until the first twenty-four hours had elapsed to perform operation, other things being equal.

The most important point is that the lowest mortality occurs when operation is performed within the six hour period. However, it may be that sometimes operation had better be deferred, just as is the case in appendicitis.

Surgical Procedure.—The type of surgical procedure has a direct bearing on mortality (fig. 5). In 148 cases

Fig. 3.—Relation of treatment to mortality.

wherein simple closure, that is, without suture of a tag of omentum over the perforation, was employed, the mortality was 34.4 per cent. In this connection it is

The Type of Operation Employed and the Complications Which Required Early Secondary Surgical Procedure in Sixteen Cases

Operation	No. of Cases	Complications	No. of Cases
Gastrojejunostomy	8	Hemorrhage	12
Simple suture	2	Obstruction	8
Pylorotomy	2	Reoperation	2
Pyloroplasty	1	Gastrojejunal ulcer	2
Jejunostomy	1		
Sleeve resection	1		
Exploration only	1		

highly important to note that in 242 cases wherein a tag of omentum was sutured over the perforation, the mortality fell off 10 per cent.

In thirteen selected cases wherein some procedure was added to closure, such as gastrojejunostomy or pyloroplasty, there were not any deaths. Two things should be taken into account with regard to this group: first, that the series is small, and second, that the patients were selected for their good general condition before the additional procedure was begun.

Drainage.—As is well known, the recent tendency is in the direction of employment of less and less drainage in acute perforation of peptic ulcer, except perhaps when purulent peritonitis is present. In a small group of fifty-seven cases wherein drainage was not employed, the mortality was 14 per cent (fig. 6). In seventy-one cases wherein a single drain to the site of the ulcer was used, the mortality was 19.7 per cent. In seventy-five cases wherein a single drain elsewhere was used, the mortality was 32 per cent. In 208 cases drainage of multiple areas was attended by a mortality of 34.4 per cent. It seems fair to point out that in the cases wherein drainage was not employed, the general condition of the patients doubtless was better and the risk of operation less than in the others, particularly those in whom multiple areas were drained.

Anesthesia.—In this series of cases only four types of anesthesia were used, namely, ether (in some instances gas followed by ether), nitrous oxide alone, and spinal and local infiltration of procaine hydrochloride (fig. 7). In the first group there were 239 cases

gastrointestinal trouble was not made on his clinical or autopsy records. The other patient was readmitted to the hospital a few months after operation with a diagnosis of senile psychosis, for which he was committed to a mental institution, from which he was reported to have died some months later.

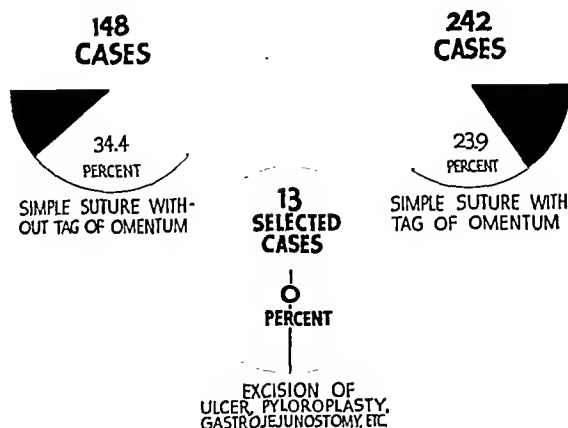

Fig. 5.—Relation of surgical procedure to mortality.

Relief.—When it was asked if complete relief was obtained after operation the affirmative was reported in nineteen cases, or 38.7 per cent, whereas incomplete relief was secured in 61.2 per cent. However, it was stated that symptoms had not persisted or recurred in only twelve cases, or 24.4 per cent. Correlation between this opinion on the part of the patient and his report of persisting symptoms was not possible from the nature of these reports.

Subsequent Treatment.—Some type of subsequent therapeutic care was required in all but twelve cases. Self medication was sufficient in twenty, or 40.8 per cent, but the care of a physician was necessary in fifteen, or

Fig. 6.—Relation of drainage to mortality.

30.6 per cent. Only two patients had had further surgical treatment. One had had a gastrojejunostomy for obstruction. The other had been symptom free for ten years when hemorrhage occurred for which gastrojejunostomy subsequently was performed. However,

Fig. 4.—Relation of the interval between perforation and operation to mortality.

in which spinal anesthesia was used with sixty-five deaths, representing a mortality of 27.1 per cent. In the second group there were 145 cases in which ether was used with forty-one deaths, or a mortality of 28.5 per cent. In this group of eighteen cases in which nitrous oxide only was used the mortality was over 10 per cent higher, with seven deaths and 38.8 per cent mortality. In the group of seven cases in which local anesthesia alone was used there were six deaths, or a mortality of 90.7 per cent.

LATE RESULTS

Owing to the shift in population among persons who make up this series of cases late follow-up study was possible in only 10 per cent. However a group of fifty-one cases allows some interesting deductions (fig. 8). The time they were followed varied from three to fifteen years. It was five years or over in thirty-four cases, or 66 per cent; four years in thirteen cases, and three years in four cases.

Deaths.—Deaths were reported in two, or 3.9 per cent, of followed cases. One patient died in the same hospital fifteen years later, at which time mention of

further surgical procedure was advised in two more cases; in one it was declined and in the other deferred because of arterial hypertension.

Disability.—Inability to work since operation was experienced in twenty-one cases, or 42.8 per cent. Disability was not experienced in twenty-eight, or 57.1 per cent.

COMMENT

The gross mortality reported in the present study in comparison with that of other reported series of cases is relatively high. This is partially explained by the fact that in over 98 per cent of cases the diagnosis of acute perforation was proved by operation or autopsy. Unless some such criterion of proof is estab-

Fig. 7.—Relation of anesthesia to mortality.

lished the inclusion of any considerable number of clinically diagnosed cases in a study of this subject will unavoidably admit cases of appendicitis, pancreatitis and cholecystitis. The results will be modified accordingly.

For the same reason the mortality in the group of patients treated expectantly is extremely high. It is fair to point out that most of the patients in this group were moribund or beyond surgical aid when first seen. None of the patients in this group were treated by the continuous siphonage method. In the group treated surgically, on the other hand, the mortality compares favorably with that of other American series.

Regarding mortality with respect to anesthesia, it should be noted that in most of the cases wherein local infiltration of procaine hydrochloride was used the condition of the patient was so poor as to make the use of other methods of anesthesia objectionable. Spinal anesthesia was the most recent addition to anesthetic procedures, and it is quite possible that the patients in this group benefited also from other recent improvements in the handling of acute perforation of peptic ulcer.

While the group of cases on which the study of late results is based is not large, it represents the most important aspect of this study.

CONCLUSIONS

From this analysis of immediate and late results of treatment in acute perforation of peptic ulcer several conclusions may be drawn:

1. The gross mortality in cases of proved acute perforation of peptic ulcer is approximately 40 per cent.
2. Mortality may be materially lowered by the application of surgical treatment.

3. Mortality is lowest when operation is performed within six hours after perforation, when spinal anesthesia is used, when the operation consists of suture of a tag of omentum over the closed perforation and when drainage is not employed.

4. In approximately 40 per cent of cases continuation or resumption of treatment is required within five years, and in 10 per cent the treatment will be surgical.

1930 Wilshire Boulevard.

ABSTRACT OF DISCUSSION

DR. DAN C. DONALD, Birmingham, Ala.: Prompt surgery in acute perforated peptic ulcer stands out in the lead of all other factors governing the mortality rate. Among the surgical procedures, simple closure of the perforated ulcer by multiple interrupted sutures incorporating the omental tag is favored by the majority of statistics, with a death rate measured chiefly by the time interval (inception of perforation until patient reaches surgery). For late results, 39 per cent of the patients with perforated peptic ulcer following simple closure continue to have ulcer symptoms, and a small percentage of the ulcers will reoperate. In consideration of late symptoms and complications of reoperation, I feel that simple closure might be altered by pyloroplasty in the duodenal and pyloric ulcer, provided the duodenum is mobile and peritonitis is not present. Through pyloroplasty I have lowered the digestive complaints to 10 per cent and the mortality rate to as low as or lower than that following simple closure. Ninety per cent of perforated peptic ulcers occur near the pylorus, and the duodenal ulcer is ten to one greater than the gastric ulcer, and rarely is it more than 2 cm. from the pylorus. In pyloroplasty the ulcer-bearing tissue is excised in an elliptic manner along the course of the bowel, incision is carried through the pyloric ring on to the stomach for 4 cm. more and the opening is closed in transversely. The advantages from this type of operation are: the ulcer is removed, pyloric spasm is overcome and the opening between the stomach and the duodenum is enlarged, permitting a reflux of the alkaline secretions from the intestinal juices to aid in minimizing the acid chyme of the stomach. The keynote of success resulting from surgery in cases of perforated ulcer of the duodenum is to permit the stomach to drain by duodenal route rather than by gastro-

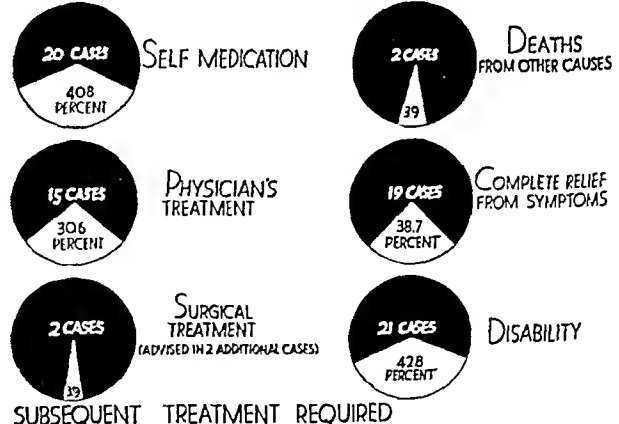

Fig. 8.—Late results in fifty-one cases followed from three to fifteen years.

jejunostomy, wherein the gastric content with a high hydrochloric acid unit is permitted to flow into the jejunum, which is often followed by a marginal ulcer. Only in definite obstruction of the duodenal type of perforated ulcer should gastrojejunostomy be considered; such perforations are rare in this entity. In all acute attacks the perforated gastric ulcer should be excised by simple closure with interrupted sutures incorporating the omental tag.

DR. J. WILLIAM THOMPSON, St. Louis: We have made a clinical study of the results in the surgical treatment of perforated peptic ulcers at the St. Louis City Hospital. Our

series of 152 cases compares in many ways with that from the Los Angeles County Hospital. The diagnosis of perforated peptic ulcer is usually not difficult. Occasionally an acutely perforated ulcer is confused with acute appendicitis. We take roentgenograms of the chest and abdomen as a routine in order to reveal the presence of air under the right leaf of the diaphragm. I believe that this is a most important procedure and should be used a great deal more frequently, especially in making a differential diagnosis in doubtful cases. Our investigations show no seasonal variation in the incidence of perforation. The mortality rate in perforated ulcer goes up tremendously in patients past the age of 60. Therefore it is important to consider surgical treatment of peptic ulcers in patients past middle age. Peptic ulcer is an extremely common disease, and familiarity should not breed contempt leading to overprolonged medical treatment. Ulcers on the gastric side of the pyloric sphincter are frequently malignant, no matter what size, and therefore should be operated on when there is the slightest doubt as to the exact nature of the lesion. In this way a few patients will be prevented from dying from complications of perforation. The procedures used in our series are essentially the same. Most of them were simple closures, and the results are better in those cases in which this method was used. The mortality rate was 25 per cent, a little lower than that of Dr. H. L. Thompson. A policy of doing more extensive operations such as pyloroplasty and gastro-enterostomy, I think, should be frowned on. In an exceptional case they are occasionally justifiable.

DR. CHARLES BROWN ODOM, New Orleans: Dr. DeBakey has reviewed 211 cases admitted to Charity Hospital in New Orleans during the last ten years. It has been recognized that the incidence of peptic ulcer is increasing. However, the frequency of acute perforation is becoming disproportionately greater. Although the percentage of ulcers per hundred thousand admissions increased from 0.0444 in 1929 to 0.0614 in 1938, comparable figures for acute perforations were 0.0139 and 0.0782. Contrary to the general impression that perforated ulcer occurs rarely in Negroes, race incidence in our series revealed almost equal frequency: 128 (60.6 per cent) white and 83 (39.3 per cent) Negro patients. Basing these respective incidences on corresponding hundred thousand admissions, these figures are: 0.0403 and 0.0364 per cent. There was no significant seasonal variation in our cases. A review of more than 15,000 cases reported in the literature revealed variations too wide to be significant. Mortality incidence in this series was found to depend on several factors, one of the most important being the number of hours after the perforation. All cases that were not proved perforations were disregarded. In eighty-two cases operation was performed within six hours with nine deaths, a mortality of 10.9 per cent; sixty-six cases within twelve hours with ten deaths, a 15.1 per cent mortality; nineteen cases within eighteen hours with five deaths, a higher mortality. After twenty-four hours there were nine deaths in nineteen cases, or 47.3 per cent. I don't believe one can treat perforated peptic ulcer any other way than by surgery. I think that Dr. Thompson's figure after the twenty-four hour period is misleading. The type of operation was another factor in the mortality rate; in 200 cases treatment was by simple closure with thirty-three deaths. With other operative procedures the mortality rate immediately increased. In seven cases in which other procedures were used three deaths occurred. The anesthetic was another factor in mortality. I believe that block anesthesia is the best anesthesia to use in these cases. Whereas of seven cases in which epidural block and 154 cases in which spinal anesthesia were used, the mortality incidences were 0 and 15.7 per cent respectively; of forty-three cases in which general anesthesia and five cases in which local analgesia were employed, the respective death rates were 22.7 per cent and 60 per cent.

DR. HAROLD LINCOLN THOMPSON, Los Angeles: The etiology, pathology and diagnosis in this group of cases have been studied statistically and are reported elsewhere. I believe that one can approach the truth in this condition only when a large series of cases is considered. I know of no other way to smooth out the marked variations that are found in reports on smaller groups of cases. I hope to make a report on a

more recent series of 500 cases in the near future. I should like to call attention again to the fact that these were proved perforations. This authentication is the only means by which to approach accuracy in a study of this kind. Regarding spinal anesthesia, it is possible, since the spinal method is the most recent addition to our methods of anesthesia, that the patients in this group also benefited by other recent technical improvements in treatment.

NEUROLOGIC ASPECTS OF HERNIATED NUCLEUS PULPOSUS

AT THE FOURTH AND FIFTH LUMBAR INTERSPACES

R. GLEN SPURLING, M.D.

LOUISVILLE, KY.

AND

F. KEITH BRADFORD, M.D.

HOUSTON, TEXAS

As recently as a year ago it was considered imperative to confirm any presumptive diagnosis of herniated nucleus pulposus of the lower lumbar intervertebral disks by roentgenologic examination of the spinal canal after injection of some contrast medium.¹ However, even a year ago in cases of severe, persistent sciatic pain associated with pain low in the back and rigidity, together with hypesthesia of the lateral aspect of the involved leg and diminution of the ankle jerk, surgical exploration gave positive results regardless of the type of defect demonstrated with iodized oil. Conversely, all too frequently in cases of what were thought to be characteristic defects demonstrable with iodized oil but in which the neurologic evidence was less characteristic, exploration gave negative results. On the basis of our experience with a series of eighty-five low intraspinal lesions treated surgically we shall present what we have found to be the characteristic clinical picture of herniated nucleus pulposus at the fourth and fifth lumbar interspaces.

The term "herniated nucleus pulposus" is used in preference to "protruded intervertebral disk" because disease of the disk is rarely responsible for nerve root compression except when the annulus fibrosus has ruptured and allowed the nucleus pulposus to extrude through the defect.

It must be emphasized in the beginning that the history and neurologic signs of herniated nucleus pulposus are not peculiar to this one clinicopathologic entity. Neoplasm along the course of the sciatic nerve, rectal or pelvic disease and disease of the osseous structures must be ruled out by regional and roentgenologic examinations before the clinical diagnosis of herniated nucleus pulposus can be made.

ANATOMIC CONSIDERATIONS

It is necessary to review the structure and innervation of the lower lumbar region to obtain a better understanding of the symptoms and signs of herniated nucleus pulposus. The relations between the fifth lumbar nerve and the disk between the fourth and fifth lumbar vertebrae and between the first sacral nerve and the lumbosacral disk are especially important, since in more

From the Department of Surgery, University of Louisville School of Medicine.

Read before the Section on Radiology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

1. Love, J. G., and Walsh, Maurice: Protruded Intervertebral Disks: Report of 100 Cases in Which Operation Was Performed, J. A. M. A. 111: 396 (July 30) 1938. Spurling, R. Glen, and Bradford, F. Keith: Low Intraspinal Lesions as a Cause of Back and Sciatic Pain, J. Med. 19: 598 (Feb.) 1939. Bell, J. C., and Spurling, R. Glen: Concerning the Diagnosis of Lesions in the Lower Spinal Canal, Radiology 31: 473 (Oct.) 1938.

than 90 per cent of the cases herniated nucleus pulposus occurs at these levels.

The spinal cord usually terminates opposite the intervertebral disk below the first lumbar vertebra. The nerve roots forming the cauda equina are freely movable in the large lumbar canal except as they approach their exits, where they are fixed. It is therefore apparent that displacement of the roots is possible, except near the port of exit, without neurologic deficit.

At the intervertebral disk between the fourth and fifth lumbar vertebrae (hereafter the fourth lumbar disk) the fifth lumbar nerve is contained in the subarachnoid space, fixed laterally against the dura one vertebra higher than its exit. The dural sleeve of the fifth lumbar nerve emerges below the fourth lumbar disk and passes downward beneath the pedicle of the fifth lumbar vertebra to its intervertebral foramen. This relation holds between all the lumbar nerves and their respective disks. In contrast, the dural sleeve of the first sacral nerve separates from the thecal sac above the lumbosacral disk and can thus be compressed without deforming the sac.

It is unnecessary to repeat the description of the intervertebral disk, so well presented by Mauric.² However, the innervation of the annulus fibrosus and the posterior longitudinal ligament which reinforces it has received scant attention.

Each of the spinal nerves gives rise to a recurrent branch just distal to the posterior root ganglion, which reenters the intervertebral foramen and supplies the ligamentous structures two vertebrae lower than the exit of the spinal nerve (fig. 1). Roofe's³ recent studies indicate that there is a profuse supply of sensory nerve endings in the annulus fibrosus and the posterior longitudinal ligament. This anatomic observation sheds much light on the symptoms both in cases in which the disease is limited to the ligamentous structures of the lower lumbar and lumbosacral regions

Fig. 1.—Distribution of the second recurrent lumbar nerve to the region of the third and fourth lumbar vertebrae and the fourth and fifth intervertebral disks.

and in cases in which a tear of the annulus fibrosus has led to herniation of the nucleus pulposus.

It is apparent from the relations indicated that knowledge of the exact distribution of the fifth lumbar and first and second sacral nerves, motor and sensory, is essential to a proper clinical understanding (figs. 2, 3, 4). In herniated nucleus pulposus the usual finding of hypesthesia or anesthesia of the lateral aspect

of the leg probably depends on the combined involvement of the dermatomes of the fifth lumbar and first sacral or the first and second sacral nerves, since the involvement of a single spinal nerve rarely gives objective sensory evidence. However, paresthesias may result from the involvement of a single spinal nerve. The dermatome of the fifth lumbar nerve is small, but its loss, with associated loss of the first sacral nerve, would probably give an area of hypesthesia on the anterolateral aspect of the leg. Similarly, both the first and the second sacral nerves would necessarily be affected if hypesthesia or anesthesia of the more lateral aspect of the leg was produced. The small gluteal dermatomes are rarely of clinical importance.

CLINICAL CONSIDERATIONS

Symptoms.—Discussion of the symptoms will be limited to those resulting from herniation of the nucleus pulposus at the fourth lumbar and lumbosacral disks.

The occurrence of severe, persistent sciatic pain is of greatest importance diagnostically, especially if it is exaggerated by coughing, sneezing or straining. The pain may not be uniform along the course of the nerve. Points of greatest intensity are likely to be in the gluteal region, the posterior aspect of the thigh, the back of the knee or the lateral aspect of the leg or ankle. Coughing, straining or sneezing may exaggerate the pain in only one place and may do so only transiently. In almost every case, however, incapacitating pain low in the back precedes the sciatic pain by weeks, months or years. In the absence of a definite history of trauma, the onset of acute pain in the back is usually associated with lifting in a bent forward position or with sudden torsion of the trunk. Frequently the pain at the time of injury is slight, becoming severe after several hours or days. The pain low in the back is variable or intermittent and is usually intensified by bending or lifting. Whether unilateral or bilateral, the main feature is its mechanical nature, its elicitation or aggravation by certain postures or movements. Additional trauma may precede extension of the pain along the course of the sciatic nerve. At this time the back pain may be an insignificant part of the clinical picture although usually present to a considerable degree.

Paresthesias are of extreme importance, being of far more localizing value than is the distribution of pain. Tingling, prickling, cold or numb sensations occurring below the knee in the lateral aspect of the leg or in the foot are characteristic of herniated nucleus pulposus at the fourth or fifth lumbar interspace.

Weakness is not usually a major complaint, being confused with the disability from pain unless a parietal palsy is present, such as foot drop.

Signs.—The stiff lumbar spine is a prominent clinical feature, but not as important diagnostically as the severe sciatic pain with a positive Lasègue sign, the hypesthesia of the foot and lateral aspect of the leg and the diminution or absence of the ankle jerk.

Fig. 2.—Approximate dermatome of the fifth lumbar root: A, ventral view; B, dorsal view; C, lateral view. (Figures 2, 3 and 4 are modified from illustrations in Tilney, Frederick, and Riley, H. A.: The Form and Functions of the Central Nervous System, New York, Paul B. Hoeber, Inc., 1938.)

2. Mauric, G.: Le disque intervertébral, Paris Thesis, 1933.
3. Roofe, Paul G.: Unpublished observations.

Patients with herniated nucleus pulposus at the fourth or fifth lumbar disk exhibit much the same appearance of the lumbar spine as patients with other severe articular disease of this region. This part of the spine is usually straight, with spasm of the erector spinae muscles, especially on bending forward. Listing to one side is common, with the ilium usually higher on the affected side. Limitation of flexion of the lumbar spine is marked in all patients in whom pain in the back is conspicuous and present to some degree in the remainder.

As Lasègue⁴ pointed out, many patients with severe sciatic pain keep the knee flexed and are unwilling to put the heel to the floor, thus preventing direct tension on the sciatic nerve. The test that bears his name accurately differentiates the patients with painful hamstring muscles from those with lesions affecting the components of the sciatic nerve. It is performed with the patient supine. The thigh is raised to right angles with the trunk, and the leg, which has remained flexed, is extended on the thigh until pain begins along the course of the sciatic nerve. Without further movement of the leg or thigh, the foot is passively dorsiflexed to determine whether this additional pull on the sciatic nerve exaggerates the pain. The results are positive in all cases of lateral herniation of the nucleus pulposus.

Occasionally, pressure directly or laterally on the spinous processes of the fourth and fifth lumbar vertebrae or pressure just lateral to the spines over the lumbar muscles will elicit pain in the distribution of the sciatic nerve. If present, this sign is highly indicative of herniated nucleus pulposus.

In a moderate percentage of patients with pain on coughing or sneezing, sustained pressure over both internal jugular veins reproduces or exaggerates the sciatic pain. This, a positive Naffziger⁵ reaction, is pathognomonic of intraspinal disease.

Tests of the motor power are usually not of much aid. Patients confuse pain on using the affected part with weakness, and testing is unsatisfactory because of the pain on exertion of motor power. However, occasionally definite paresis or paralysis of the anterior tibial, peroneal, extensor hallucis or extensor digitorum

the leg will be hypesthetic in most cases. However, herniation at the fourth lumbar disk (involvement of the fifth lumbar and first sacral nerves) usually results in hypesthesia of the anterolateral aspect of the leg with inclusion of the great toe (figs. 2 and 3), while herniation at the lumbosacral disk (involvement of the first and second sacral nerves) gives hypesthesia of the

Fig. 4.—Approximate dermatome of the second sacral root. A, ventral view; B, lateral view; C, dorsal view; D, mesial view.

posterolateral aspect of the leg with inclusion of the lateral aspect of the foot (figs. 3 and 4). Sensory changes may also extend to the posterior aspect of the thigh and the saddle region on one side, but, as a rule, no diminution is observed above the knee. Although the areas of hypesthesia can usually be determined with pinprick, testing with cotton wool or hot and cold test tubes frequently reveals a definite area of hypesthesia where results with pinprick were equivocal. Stimulation of the hypesthetic zone may produce typical causalgic pain, limited to the area involved. The causalgia may overshadow the hypesthesia.

Patients with herniation of the nucleus pulposus at the fourth lumbar and the lumbosacral disk have in common pain low in the back, severe sciatic pain, and hypesthesia or anesthesia below the knee. If the ankle jerk is unchanged and paresthesia or hypesthesia in the leg is more anterior, including the great toe, the fourth lumbar disk is more likely involved. If the ankle jerk is diminished or absent and the hypesthesia is more posterolateral, including the lateral aspect of the foot, the herniation is probably at the lumbosacral disk.

COMMENT

The recurrent episodes of pain low in the back which usually precede the sciatic pain of herniated nucleus pulposus are due to disease of the intervertebral disks and posterior longitudinal ligament. Tearing of these structures may result from frank trauma or as a result of "wear and tear" on already degenerated structures. The annulus fibrosus and posterior longitudinal ligament are innervated by the recurrent branches of the lumbar nerves. Pain predominates locally with perhaps some spread to the gluteal regions or upper posterior aspect of the thighs. But true sciatic pain is not caused by involvement of the ligamentous structures alone. Many patients with ligamentous injuries probably recover without herniated nucleus pulposus developing beneath the nerve roots. It must be remembered that if the nucleus pulposus extrudes through the annulus fibrosus without causing nerve compression the lesion remains in the category of purely ligamentous injury.

However, in patients with disease of the annulus fibrosus, herniation is likely to occur in a posterolateral direction because of the poor lateral development of the posterior longitudinal ligament which reinforces the

Fig. 3.—Approximate dermatome of the first sacral root: A, ventral view; B, lateral view; C, dorsal view; D, mesial view.

communis muscles is seen. Fibrillation of muscles of the leg is also seen in some cases. Much more important is diminution or absence of the ankle jerk, which usually occurs with herniation at the lumbosacral disk.

The sensory changes are most important in making the diagnosis. Whether the herniation is at the fourth lumbar or the lumbosacral disk, the lateral aspect of

4. Lasègue, Ernst-Charles: Consideration sur la sciatique, *Arch. gén. de méd.*, 2: 558, 1864.

5. Naffziger, H. C., and Jones, O. W.: Dermoid Tumors of the Spinal Cord, *Arch. Neurol. & Psychiat.*, 33: 941 (May) 1935.

annulus fibrosus. At the fourth lumbar disk such a posterolateral herniation compresses primarily the fifth lumbar nerve just above its exit through the dural sleeve. If it extends far laterally, it can and does, rarely, compress the fourth lumbar nerve in its foramen. If it extends medially, compressing the thecal sac from the side, in addition to the fifth lumbar nerve, it will compress the first and perhaps the second sacral nerve, only displacing the other roots, whose fixation points of exit are lower or on the opposite side. At either the fourth lumbar or the lumbosacral disk an occasional herniation is sufficiently large to compress a number of roots against the ligamentum flavum or the lamina, thereby producing more diffuse signs.

The first sacral nerve can be compressed by such a posterolateral herniation without any indentation of the dura mater, since its dural sleeve emerges above the lumbosacral disk. Although herniation rarely extends far enough laterally to involve the fifth lumbar nerve, this can occur. Far more common is compression of the dural sac in addition to compression of the first sacral root, with resulting involvement of the second and perhaps the third, fourth and fifth sacral roots.

It is the compression of one or more of these components of the sciatic nerve which gives rise to the severe "sciatica." From involvement of either the fifth lumbar or the first sacral root alone, pain can occur along the course of the entire nerve. The sensory as well as the motor innervation of the glutei, hamstrings and leg muscles is contributed to by both these nerves, which explains pain in these muscles. The absence of pain in the iliopsoas, quadriceps femoris and adductors is explained by their higher segmental innervation.

Although pain does occur in the dermatomes of the involved spinal nerves, it is more often lacking. Paresthesias are far more frequent and important in accurate clinical localization especially when coupled with objective sensory signs. Only in exceptional instances is paresthesia or hypesthesia of the gluteal portions of the dermatomes of the fifth lumbar and first and second sacral nerves observed.

The usual absence of involvement of the ankle jerk in herniation at the fourth lumbar disk (involvement of the fifth lumbar nerve) and diminution (involvement of the first sacral nerve) or absence (involvement of the first and second sacral nerves) in herniations at the lumbosacral disk are in keeping with the accepted innervation of the gastrocnemius and soleus muscles by the first and second sacral nerves. Confusing is the fact that these muscles have rarely been found weak and never paralyzed in cases of herniation of the nucleus pulposus.

That these neurologic symptoms and signs are accurate and reliable is attested by the fact that during the past three months we have successfully removed nine consecutive herniations of the nucleus pulposus without confirmation with iodized oil or other contrast mediums. In the same three months iodized oil was used six times, with indication for operation in but two instances. Even in these two cases the clinical evidence pointed with reasonable certainty to the location of the lesion, but as compensation was involved in both cases verification with iodized oil was deemed advisable. The present high incidence of positive results of exploration, in contrast to our earlier results,⁶ we owe chiefly to the increased understanding of the neurologic picture.

6. Bradford, F. Keith, and Spurling, R. Glen: *Intraspinal Causes of Low Back and Sciatic Pain: Results in Sixty Consecutive Low Lumbar Laminectomies*, Surg., Gynec. & Obst., to be published.

SUMMARY

1. Although herniated nucleus pulposus of the fourth lumbar and the lumbosacral disk has long appeared to give an unorthodox neurologic picture, a more thorough experience with this lesion has made possible accurate diagnosis from clinical evidence alone in the majority of instances.

2. The neurologic signs of herniated nucleus pulposus are not peculiar to this clinical entity, since neoplasm along the course of the sciatic nerve, pelvic and rectal disease and disease of the osseous structures may simulate the clinical picture.

THE DIAGNOSIS OF INTERVERTEBRAL DISK PROTRUSION BY INTRA-SPINAL INJECTION OF AIR

AIR MYELOGRAPHY

W. EDWARD CHAMBERLAIN, M.D.

AND

BARTON R. YOUNG, M.D.

PHILADELPHIA

Air or oxygen serves as an excellent contrast medium in the spinal canal for visualization of a protruded intervertebral disk or any other space-taking lesion. We have used gaseous contrast mediums as a routine for the past three and one-half years with all patients who have had sufficient symptoms and neurologic evidence to make us suspect an intraspinal lesion.¹ Our experience, based on more than 300 spinograms, indicates that the method is accurate and reliable, as in each case in which operation was performed the

Fig. 1.—Normal lumbocaudal sac. Note the sharp definition of the lateral margins of the sac as seen on the anteroposterior projection with the patient in the Trendelenburg position.

exact level of the lesion determined by myelographic examination was verified by laminectomy. The procedure is harmless, so negative results cause no feeling of apprehension as to unpleasant or dangerous sequelae, such as might develop if the contrast medium were an unabsorbable substance.

The use of air in the spinal canal was suggested by Dandy² in 1918, but only in recent years has it been possible to obtain sufficient contrast and detail in roentgenograms to utilize gaseous contrast mediums.

From the Department of Radiology, Temple University School of Medicine.

Read before the Section on Radiology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

1. We have used oxygen as a routine for more than a year because it is absorbed faster than air and produces less discomfort.

2. Dandy, W. E.: *Ann. Surg.* 68: 5 (July) 1918.

In 1934 Coggeshall and von Storch³ showed that the lumbocaudal sac could be visualized by air, but their report was limited to the results with three normal patients. The same year Van Wagenen⁴ reported three cases of complete spinal block in which the lower level of the lesion was visualized by injection of small amounts of air. During the past year we and our associates have reported our use of myelographic examination with air and oxygen in a number of articles.⁵

The technic of injection varies somewhat, depending on the level of the lesion. If a lesion is suspected below the third lumbar vertebra, the patient is placed in a lateral decubitus position, with the head of the table lowered to an angle of from 20 to 25 degrees. An 18 or 20 gage spinal needle is inserted into the subarachnoid space at the second lumbar interspace, and spinal fluid and air are exchanged in 5 cc. quantities until air escapes through the needle. Usually it takes from 40 to 50 cc. to fill the lumbocaudal sac in the adult (fig. 1). In case the clinical evidence places the lesion above the third lumbar vertebra, the spinal needle is inserted in the third lumbar interspace with the patient in a horizontal position and a Queckenstedt test is done. If this

Fig. 2.—Unilateral marginal indentation at the fifth lumbar interspace due to a protruded intervertebral disk. A hypertrophied ligamentum flavum may produce a similar defect. There were complete disappearance of the pain and restitution of function after removal of the disk.

test shows a partial or complete block, from 3 to 6 cc. of spinal fluid is carefully replaced by an equal amount of air so that the spinal fluid pressure is kept as constant as possible. The patient is then placed in the sitting posture with his back against a Potter-Bucky diaphragm for the roentgenograms.

If the Queckenstedt test is negative, the dorsal sac can be visualized by replacement of spinal fluid with air by either lumbar or cisternal puncture. Nearly all our patients had air introduced after lumbar puncture because we are especially interested in the lumbocaudal sac and have examined this area as a routine (even though the signs pointed to a lesion in the dorsal region) in order to obtain normal standards. If the lumbocaudal sac is well filled there will be sufficient air for visualization of the dorsal sac, but in order to get the air into the dorsal region the patient is turned face down and the table changed from the Trendelenburg to the horizontal position. To visualize the subarachnoid

space in the cervical region it is necessary to do either cisternal puncture with the patient in the Trendelenburg position or lumbar puncture with complete drainage of the cerebrospinal fluid as in encephalography.

Visualization of air in the spinal canal depends on roentgenograms of good contrast and detail. We have found that "overexposed" films give us more informa-

Fig. 3.—Normal posterior bulging of the ventral limiting membrane of the lumbocaudal sac seen opposite each intervertebral disk when the patient is in hyperextension. Hyperflexion produces flattening or straightening of this ventral membrane.

tion, so we raise the kilovoltage from 8 to 10 above that necessary for spinal detail. An ordinary horizontal x-ray table equipped with a Potter-Bucky diaphragm is used and, in order to get the necessary Trendelenburg position, one end is elevated by a chair or blocks. The minimal film requirements in the lumbar region are stereoscopic lateral and anteroposterior projections. When the interest is centered in the upper dorsal or cervical region, it is advisable to take stereoscopic oblique projections as well as the lateral ones, because

Fig. 4.—Displacement of the posterior longitudinal ligament dorsad by a herniated intervertebral disk at the fourth lumbar interspace. (Compare with the normal configuration of fig. 3.) Note the narrowing of the interspace. At operation the sac below the protruded disk was almost obliterated by the resultant arachnoiditis.

the superposed shadow of air in the trachea often interferes with interpretation. The normal dorsal curve will cause the air to remain below the fourth or fifth dorsal segment, so the upper part of the thorax should be elevated by small pillows or sand bags under the shoulders, but the head must be lower than the air column or air will ascend into the cranium and produce headache.

We have been interested in the effects of hyperflexion and hyperextension on the configuration of the ventral limiting membrane of the lumbocaudal sac. For this reason, as a routine we make additional stereoscopic lateral projections of the lumbar region in these special positions. In every normal case the maneuver of hyperflexion is seen to flatten the contours of the ventral surface of the sac, while hyperextension produces plainly visible bulging of soft tissue contours into the canal opposite each intervertebral disk. In a few cases of intervertebral disk protrusion we have obtained some evidence of accentuation of the disturbance during extension of the spine and partial reduction of the protrusion during flexion. Further studies along these lines are being carried out.

The diagnosis of a herniated disk depends in most cases on the indentation or encroachment of the limiting membrane of the subarachnoid space. The one exception to this is seen when the disk has produced a complete block of the canal and, if this is the case, the inferior margin of the disk is easily demarcated by the air bubble trapped under it (fig. 5). A herniated disk nearly always carries the posterior longitudinal ligament dorsad so that the indentation of the ventral aspect of the air column is usually detected on the lateral projections (fig. 3). Commonly the defect is noted at the level of the interspace, but if the protrusion is marked the ventral limiting membrane of the canal will be pushed dorsad for a variable distance below the interspace (fig. 4). The indentation of the air column due to a herniated disk is not always seen on the lateral

Fig. 5.—Herniated intervertebral disk producing incomplete block of the subarachnoid space at the fourth cervical segment. Three cc. of air trapped under the disk revealed its level. The disk was removed at laminectomy. The roentgenograms were taken immediately after the patient was placed in an upright sitting position.

projections. In a number of cases the defect was visualized only on the anteroposterior projections as a bilateral waistlike constriction or a unilateral marginal indentation (fig. 5).

SUMMARY AND CONCLUSIONS

Myelographic examination with air is a reliable and harmless method of visualizing herniated intervertebral disks and other space-taking lesions in the spinal canal. The success of the method depends on proper technic of air injection and roentgenograms of good contrast and detail. We have had experience with more than 300 spinograms for which air or oxygen was the contrast medium. We consider the method reliable because in every case in which operation was performed the level of the lesion predicted after myelographic examination was verified at laminectomy. Air studies have not been misleading, as there were no instances in which

the myelograms indicated a lesion without verification at operation.

A major advantage of air and oxygen as contrast mediums for myelographic examination is the fact that their use does not entail leaving unabsorbable and possibly irritating substances in the spinal canal. Even those who believe that iodized oil is not contraindicated for myelographic examination tend to reserve its use to cases in which laminectomy is practically assured at the time of the study. Because air and oxygen are completely absorbed from the subarachnoid space (oxygen more promptly than air) there will be less hesitancy about subjecting patients to myelographic examination with such a contrast medium.

THE ROENTGENOLOGIC DIAGNOSIS OF INTRASPINAL PROTRUSION OF INTERVERTEBRAL DISKS

BY MEANS OF RADIOPAQUE OIL

JOHN D. CAMP, M.D.

ROCHESTER, MINN.

Since Mixter and Barr¹ in 1934 emphasized the significance of intraspinal protrusion of the intervertebral disks as an important cause of low back pain and sciatica, this condition has aroused no little interest. During the past few years considerable literature concerning the subject has appeared and the condition has been firmly established as a definite clinical and pathologic entity. Pathologic studies of a large series of protruded intervertebral disks by Deucher and Love² indicate that the protruded fragments are composed of fibrocartilage, portions of the nucleus pulposus and occasionally remnants of the notochord. These structures are not ordinarily opaque to roentgen rays and cannot be demonstrated per se in plain roentgenograms. Bone or calcium in quantities gross enough to be revealed roentgenographically is so rare in these protrusions that it is of little practical diagnostic importance.

For this reason the roentgenologist is dependent on the use of some contrast agent for the indirect visualization of the protrusion. Several contrast agents, that is, iodized poppyseed oil,³ air⁴ or oxygen, skiodan,⁵ and colloidal thorium dioxide,⁶ have been employed for visualization of the spinal subarachnoid space. Each of these substances has certain advantages and disadvantages. None of them so far have proved ideal and sooner or later a nonirritating radiopaque agent that can be absorbed and eliminated through the spinal fluid will be developed. Such a substance should do much to expand the usefulness of roentgenologic procedures in the study of neurologic conditions.

To date iodized oil has been used more than any other contrast agent for the roentgenologic visualization of

the spinal subarachnoid space and when employed under proper circumstances it has resulted in an accuracy of diagnosis that is shared by few other roentgenologic procedures. The chief objection to the use of iodized oil is that it is more or less of an irritant to the meninges and is contraindicated in the presence of inflammatory disease. The significance of the irritative action has been discussed pro and con in the literature for some years but nevertheless it is the consensus of observers who have used it in a large number of cases that in properly selected cases the advantages of its use far outweigh any disadvantages that are known.

I have had no experience with the use of colloidal thorium dioxide for visualization of the subarachnoid space. It is very irritating to the cerebral meninges, especially the ependyma, and it is very probable that it has the same effect on the spinal meninges. The fact that it is radioactive and has not been accepted by the Council on Pharmacy and Chemistry of the

American Medical Association makes it a drug to be used with considerable discretion despite its desirability from the standpoint of radiopacity alone.

Fig. 1.—Protruded lumbosacral intervertebral disk. Classic unilateral deformity of iodized oil shadow.

The use of air or oxygen for the study of the spinal subarachnoid space has been revived in recent years and this procedure has much in its favor.⁷ On the other hand there are certain decided disadvantages. In the first place, because of the difficulty in controlling the position and distribution of the air (or oxygen) its use with any satisfaction is restricted to the lumbar canal. Secondly, the accuracy of the diagnosis with air is not equal to that attained with iodized oil. My own experience with the use of air as a substitute for iodized oil in the case of lesions associated with low back pain or sciatic pain indicates that iodized oil is more accurate, that it will reveal certain structures not demonstrated with air, and that it has localized lesions that air has failed to disclose. There is no doubt that air will reveal some lesions very satisfactorily and can be used in many instances before iodized oil is resorted to. However, the results of such an examination following the use of air should be carefully appraised by the clinician in view of the limitations of its accuracy.

INDICATIONS FOR THE USE OF IODIZED OIL

The indiscriminate use of iodized oil in cases of low back or sciatic pain is not recommended. No contrast agent should be used unless the clinical and neurologic examination indicates the possible presence of an intraspinal lesion that cannot be localized by ordinary clinical procedures. Increasing familiarity with the history and neurologic examination in cases of protruded intervertebral disks indicates that in a fair proportion of cases the diagnosis and localization of the protrusion can be made clinically without resorting to any contrast agent.⁸ With this improvement in clinical diagnostic acumen the necessity for the use of a contrast

agent will probably diminish and be reserved for those cases in which the diagnosis is in doubt and those in which it is desirable to establish a very precise anatomic level of the lesion for the guidance of the neurosurgeon.

If the suspected level of a lesion is at the conus or above, experience indicates that the use of air or oxygen will not be helpful unless obstruction of the subarachnoid space has occurred. This results from the fact that air or oxygen is very difficult to hold in position in the thoracic or cervical portion of the spinal canal, and their use in these regions is further complicated by the superimposition of the shadow of air in the trachea, larynx and pharynx, which renders the interpretation of resulting shadows exceedingly difficult or impossible. Iodized oil, therefore, is the medium of choice for the demonstration of lesions at or above the conus.

Statistics indicate that the great majority of protruded intervertebral disks occur in the lumbar and lumbosacral regions where they are accessible to exami-

nation by either air or iodized oil.⁹ Since there is a reasonable chance that the protrusions may be disclosed by air or oxygen, it is probably good judgment to attempt their localization by this means before iodized oil is resorted to. If the air studies are inconclusive or unsatisfactory, iodized oil may then be used. If the air studies are negative and the history and neurologic examination are suggestive of the presence of a protruded disk, iodized oil should be used to check the spinogram. When the air studies reveal either a deformity that will not account for the patient's symp-

Fig. 2.—Central type of protruded intervertebral disk. Various deformities occurring in the same case: (a) Deformity of iodized oil that results when oil is allowed to collect above and below the protrusion. obstructing lesions, but the neurologic examination in these cases usually gives results that nowadays the level can be established without the use of iodized oil.

Fig. 3.—Protruded intervertebral disk. Bilateral type of iodized oil deformity.

The majority of protruded intervertebral disks do not produce obstruction and 12 per cent of protruded intervertebral disks in my experience have been

In the interest of early diagnosis and for the localization of lesions before obstruction has occurred, it is necessary to use a quantity of iodized oil sufficient to fill the subarachnoid space completely at any desired level. For several years I have advocated the use of 5 cc. of iodized oil because I have found from previous experience with smaller amounts that this is the optimal volume for accurate and consistent localization of nonobstructing lesions.¹⁰ Some lesions can be shown with lesser quantities but on the other hand a number of surprisingly large lesions and particularly multiple lesions are easily overlooked if amounts less than 5 cc. are used.

though the majority occur in a region of the spinal column that is easily examined. In my experience, reactions following the injection of 5 cc. have been no greater than those observed with 2 cc.

TECHNIC OF INJECTION

The lumbar injection of iodized oil is preferred because it is easier and safer to carry out than cisternal puncture and will facilitate the keeping of the oil together as one mass in the lower part of the spinal column—a point that is very important for the demonstration of small lesions. It is important that the iodized oil used be clear, transparent and only faintly yellow. Oil that is brownish should be discarded, since this indicates deterioration and the presence of free iodine, which is undesirable. Prior to injection the ampule is warmed to a temperature of 105 F., which will increase the fluidity of the oil and facilitate its injection. If the

The deformity is more marked on the left side.

multiple, as shown in the table. For this reason I still believe that 5 cc. of iodized oil is the optimal amount to use for the demonstration of protruded disks even

injection is made with slow continuous pressure on the syringe, droplet formation within the subarachnoid space will be avoided.

ROENTGENOLOGIC TECHNIC

It is desirable that the roentgenologic study be carried out as soon after the injection as possible, as delayed examination and movements of the patient may lead to separation of the mass of oil and droplet formation. A tilting fluoroscopic table with appropriate foot and shoulder rests is necessary for the roentgenologic examination. Some method of quickly recording the fluoroscopic image on films is highly desirable. If a spot film device is not available, excellent films may be made by sliding a cassette under the fluoroscopic screen, delimiting the area by the fluoroscopic shutters and changing from fluoroscopic to radiographic technic by means of a quick change-over switch on the control panel. In addition to localized "spot" films of the lesion, a large film revealing several contiguous vertebrae is

10. Camp, J. D.; Adson, A. W., and Shugrue, J. J.: Roentgenographic Findings Associated with Tumors of the Spinal Column, Spinal Cord and Associated Tissues, *Am. J. Cancer* 17: 348-372 (Feb.) 1933. necessary in order to establish the anatomic level accurately. This is extremely important when surgical intervention is contemplated, because congenital variations at the lumbosacral junction or the presence of additional lumbar vertebrae may easily mislead the surgeon when counting spinous processes to determine the site for laminectomy.

The details concerning the actual technic of the roentgenologic examination for determining the presence of a protruded intervertebral disk have been published previously and will not be repeated here.¹¹ If the result of the examination of the lumbar spinal subarachnoid space is negative, I believe that it is important to examine the subarachnoid space higher up, as recent observations⁹ have revealed that 50 per cent of patients with tumors of the spinal cord located in the thoracic region and 30 per cent of patients with such tumors located in the cervical region have low back or sciatic pain or both as an associated or coincident symptom. Quantities of iodized oil less than 5 cc. are not practical for this phase of the examination because, smaller masses of oil are rapidly diminished in size by the droplets that normally separate out and lag behind as the oil moves cephalad through the thoracic region. The quantity thus remaining for study of the upper thoracic and cervical regions is totally insufficient to portray even a large protruded disk.

ROENTGENOLOGIC CHARACTERISTICS OF PROTRUDED INTERVERTEBRAL DISKS

The deformity of the iodized oil shadow resulting from a protruded intervertebral disk is influenced by the following factors: (1) the position of the protrusion, (2) size of the protrusion, (3) associated hypertrophy of the ligamentum flavum, (4) changes in the nerve roots (displacement, edema, nonfilling of affected nerve root sleeve) and (5) anatomic variations of the cul-de-sac.

Position of the Protrusion.—Except in very unusual cases the protruded fragment is situated in the anterior portion of the spinal canal and will produce its maximal effect on the column of iodized oil when the patient is lying in a prone or prone-oblique position. Since the majority of protruded intervertebral disks present on one side of the median line, the classic defect is a sharply defined unilateral rounded indentation of the iodized oil shadow opposite an intervertebral disk (fig. 1). It occurs in about 65 per cent of cases. Midline protrusions when of moderate size may produce only a central defect. They are most obvious when some of the oil is allowed to accumulate just above and just below the

lesion (fig. 2 a). When the table is elevated and a large quantity of iodized oil is permitted to flow over the point of maximal protrusion, the central defect may appear to be obliterated and convey the erroneous impression that the region is normal (fig. 2 b). Repeated observations at the site of such lesions will reveal that the central defect will reappear whenever the oil is allowed to move slowly away from the protrusion and uncover the "hump" produced by the lesion. In the prone-oblique or lateral position the defect of a central protrusion will be quite obvious and the shadow of the iodized oil that passes over the peak of the protrusion will be clearly defined (fig. 2 c). Large central protrusions are easily recognized because the deformity that they produce cannot be effaced regardless of the amount of iodized oil at the site of the lesion. Partial obstruction is common in large central lesions.

Size of the Protrusion.—The extent of the iodized oil defect is influenced naturally by the size of the protrusion. Any deformity to be of diagnostic significance must be persistent, although the extent of the deformity may be somewhat influenced by the volume of iodized oil at the site of the lesion. In contrast to central protrusions, unilateral lesions are usually most obvious when a large mass of oil is present about it. Except as the iodized oil deformity may be influenced by the presence of associated hypertrophy of the ligamentum flavum, the larger the protrusion the greater the obstruction of the subarachnoid space will be. Partial obstruction occurs in about 11 per cent of cases and complete obstruction in only about 2.5 per cent of cases. The larger the protrusion the greater the tendency to produce a bilateral deformity, which occurs in about 35 per cent of cases (fig. 3). The presence or absence of a bilateral deformity is also influenced considerably by the presence or absence of hypertrophy of the ligamentum flavum.

Hypertrophy of the Ligamentum Flavum.

This condition has been found frequently by neurosurgeons in conjunction with a protruded intervertebral disk. It generally occurs at the same level as the protrusion but may occasionally be found at other interspaces. Localized hypertrophy of the ligamentum flavum without coincident protrusion of a disk is not common, but when it does occur it may imitate all the clinical phenomena of a protruded intervertebral disk. Normally the ligamentum flavum forms the posterior boundary of the intervertebral foramen and extends posteriorly on each side to the midline, thus enclosing the spinal canal between the laminae.

Fig. 6.—Protruded intervertebral disk between fourth and fifth lumbar vertebrae. Iodized oil deformity is on the right side. Defect due to edema of affected nerve root and obliteration of usual shadow of nerve sleeve is indicated by arrow. Note normal shadow of nerve sleeve on opposite side.

D.: Root Pain Resulting from Intraspinal Protrusion of Intervertebral Disks: Diagnosis and Surgical Treatment. J. Bone & Joint Surg. 19: 776-804 (July) 1937.

Because of the anatomic location of the ligamentum flavum, this structure when it hypertrophies will compress the column of iodized oil posteriorly and laterally. Hypertrophy of the ligamentum flavum, when it occurs without associated protrusion of an intervertebral disk, is characterized in the lateral view by a broad or rounded indentation on the posterior aspect of the

Fig. 8.—Protruded lumbosacral intervertebral disk. Iodized oil reveals narrow cul-de-sac and also slight indentation on right side at site of protrusion.

column of iodized oil between contiguous laminae⁹ (fig. 4a). In the prone or supine position the hypertrophy may be portrayed by broad indentation of the column of iodized oil, sometimes unilateral but generally bilateral (fig. 4b). There is no constant relation between the degree of hypertrophy of the ligamentum flavum and the size of the associated protruded intervertebral disk. It is not uncommon to find a marked hypertrophy of the ligamentum flavum in association with a moderate protrusion of the disk, and under such circumstances the defect produced by the ligamentum flavum is the predominant part of the visible deformity.

Because of the size and extent of the normal ligamentum flavum, the iodized oil deformity that results when it hypertrophies will extend over a longer area than that occupied by the contiguous intervertebral space and the area occupied by a protruded disk unless the disk fragment is unusually large. Early in this work, before the significance of hypertrophy of the ligamentum flavum was recognized, it was sometimes difficult to reconcile the large iodized oil deformity in certain cases with the small protruded disk that was found at operation. It is now clear that the defect was largely the result of a hypertrophied ligament, the deformity of which was not recognized.

When considerable hypertrophy of the ligamentum flavum accompanies a large protruded disk, the iodized oil defect is characteristic. The mass of iodized oil is compressed between the protruded disk anteriorly and the hypertrophied ligamentum flavum posteriorly and laterally. The resultant deformity is shown in figure 5a and b. The narrow streak of iodized oil in the midline represents the small quantity of oil that remains beneath the angle posteriorly where the right and left halves of the ligament meet. The upper and lower limits of the defect are sharply defined owing to the termination of the ligamentum flavum along its point of insertion on the contiguous laminae.

Changes in the Shadows of Nerve Roots.—The shadows of nerve roots composing the cauda equina are frequently visualized in the roentgenograms that are made during the course of the study with iodized oil. In about one third of the cases of protruded intervertebral disk, lateral or posterior displacement of the nerve root shadows or both will be visible at the site of the protrusion. The presence of such changes is helpful in supporting a diagnosis of protruded inter-

vertebral disk when the other iodized oil appearances are atypical or are minimal in extent.

Edema of Contiguous Nerve Roots.—The significant symptoms of a protruded disk are the result of pressure exerted on the nerve roots by the protruded fragments. Edema of an affected nerve root may result in three ways: (1) by irritation of the root as it passes over the protruded disk, (2) by compression of the root between a protruded disk and the contiguous pedicle of the vertebra or (3) by compression of the root between a protruded disk and a hypertrophied ligamentum flavum either within the spinal canal or at the point of emergence through the intervertebral foramen. In the latter case pressure on the nerve is further increased by narrowing of the intervertebral foramen, which results from the hypertrophied ligamentum flavum which forms its posterior boundary. The edematous nerve root will displace additional iodized oil at the site of protrusion and correspondingly increase the deformity. An early change resulting from edema of a nerve root is obliteration of the usual shadow of the nerve sleeve where the root passes through the dura (fig. 6). In some cases the shadow of an edematous nerve root may extend one or more segments above the level of the protrusion (fig. 7). anomalies of the terminal portion of the cul-de-sac, which occur in about 5 per cent of cases, may complicate the roentgenologic diagnosis of a protruded

Anatomic Variations of the Cul-de-Sac.—Two lumbosacral intervertebral disk. The first of these is an anomaly in which the cul-de-sac terminates at the usual site about the level of the second sacral segment but is considerably narrower than normal below the level of the fourth lumbar intervertebral space (fig. 8). In such a case a moderate protrusion of a lumbosacral

Fig. 9.—Protruded intervertebral disk between fourth and fifth lumbar vertebrae. Note absence of shadow of nerve sleeve at site of protrusion. Anomaly of the cul-de-sac, which is short and terminates just below the lumbosacral interspace. Compare with figure 1, in which the cul-de-sac presents the usual normal appearance.

disk may be present without deforming the iodized oil in the narrow subarachnoid space and a large protrusion may produce only a minimal defect. The second anomaly is one in which the cul-de-sac terminates one or two segments more cephalad than usual with or without a variation in its diameter (fig. 9). In a few instances the cul-de-sac will terminate above the level of the lumbosacral interspace. In the presence of either condition but especially of the latter, it is obvious that a lumbosacral protrusion may not be disclosed by iodized oil or any other contrast agent. When such anomalies are present and the iodized oil examination is found to be negative, the roentgenologist should state that the presence of a protruded lumbosacral intervertebral disk cannot be excluded. This is important, because if the history and physical signs indicate the probable presence of a protruded intervertebral disk, an exploratory laminectomy over the lumbosacral interspace may be advisable.

ACCURACY OF THE METHOD

In a series of 203 cases in which laminectomy was performed and in which a roentgenologic diagnosis of protruded intervertebral disk had been made, the diagnosis was confirmed by the surgeon in 194 instances.⁹ In one case no lesion was found to account for the iodized oil deformity (error of commission). In eight instances a lesion other than a protruded disk was found by the surgeon (error of interpretation) and they may be listed as follows: chronic arachnoiditis with contraction of the dura, one; fracture of a twelfth thoracic facet, one; vascular tumor, varices and so on, four; hypertrophied ligamentum flavum, one; neurofibroma, one. In the same period a protruded intervertebral disk was found by the surgeon in seven other cases in which the iodized oil examination had been reported as negative. It is interesting that all of these occurred at the lumbosacral junction, where there is a very good anatomic reason for the error. At this level the spinal canal is relatively large and the diameter of the caudal sac may be small because of its fusiform termination. Under such circumstances even a large protruded disk may exist without indenting the sac. In five of these seven cases an anomaly of the cul-de-sac, as referred to, was present. It is obvious therefore that the iodized oil studies revealed the presence or absence of a protruded intervertebral disk with an accuracy of 92.3 per cent in a series of 210 cases on which operation was performed.

PROTRUDED INTERVERTEBRAL DISKS

WITH A NOTE REGARDING HYPERTROPHY OF LIGAMENTA FLAVA

J. GRAFTON LOVE, M.D.
ROCHESTER, MINN.

Protrusion of intervertebral disks into the spinal canal is a subject that has been much discussed during the recent few years.¹ That it should assume a large place in our daily efforts to relieve pain and suffering is justified because of the frequency with which we are called on to treat intractable low back and sciatic pain, which often is an expression of protrusion of an intervertebral disk or disks in the lumbar region of the spinal column. The protrusion of a portion of one or more intervertebral fibrocartilages, with the consequent compression of the spinal cord or of one or more nerve roots, provides us with a real anatomic and pathologic explanation for the disability experienced by many patients. Such an explanation has been sorely needed. Too many patients have been treated, all too often unsuccessfully, for such incorrect and meaningless diagnoses as "lumbosacral strain," "sacro-iliac dislocation," "sciatic scoliosis," "sciatic neuritis" and "lumbago."

Before proceeding further I should like to make myself clear regarding the frequency of the condition of protruded intervertebral disk which we are today able to diagnose accurately, and I should like to warn against considering every case of low back and sciatic pain a case of protruded disk. There are many other causes of pain in the lower part of the back and for pain which extends into one or both lower extremities.

At the Mayo Clinic, every person with low back and sciatic pain is seen by an orthopedic consultant either

before the patient is referred to the neurologic section or in consultation with the neurosurgeon. Dr. Henderson² has collected figures from the cross-index filing system of the clinic which show that during the years 1935, 1936 and 1937 only 1.8 per cent of the patients seen by the orthopedic consultants because of low back and/or sciatic pain underwent laminectomy because of a diagnosis of protruded intervertebral disk. After the patients have been given their general physical and orthopedic examinations and the majority of those having low back and sciatic pain have been segregated, so to speak, only about 40 per cent of the patients suspected of having an intraspinal lesion as the causative factor in the complaint and referred to the neurologic section for further investigation come to operation for protruded intervertebral disk at the hands of the neurosurgeons.³

With this as an introduction to general discussion, the analysis of our more than 300 proved operative cases should excite no alarm about what might be considered our "radical" treatment of sciatic pain. In fact, it would seem that evidence is sufficient to justify the statement that laminectomy accompanied by removal of the protruded portion of an intervertebral disk is possibly the least radical of any known curative treatment for such a disabling condition.

During the past few years our experience with protruded intervertebral disks has been so extensive that we have been able, after a careful analytic study, to formulate a characteristic symptom complex for the lumbar lesions.²

A patient presenting himself for treatment with a complaint of intractable low back and sciatic pain, and who on examination exhibits spasm of the lumbar muscles, loss of the normal lumbar lordosis, positive Lasègue's and Kernig's signs, sciatic tenderness and diminution or absence of the homolateral achilles tendon reflex, is very likely to be suffering from a protruded intervertebral disk. If, in addition, there is a moderate elevation of the total protein content of the cerebrospinal fluid obtained on puncture in the lower part of the lumbar segment, and if there is a narrowing of the fourth or fifth lumbar intervertebral space, the picture is complete and a diagnosis of protrusion of a

Read before the Section on Radiology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.
1. Articles on the subject (continued in next column):

lumbar disk is justified. I have removed by surgical intervention at the time of laminectomy a classic protrusion of the disk in ten such cases without the use of radiopaque oil. Dr. Craig,⁴ up to Dec. 9, 1938, had operated in twenty-seven cases in which the clinical diagnosis was made without the use of a contrast medium.

Fig. 1.—Anteroposterior view after operation showing the small amount of the laminae of the fifth lumbar vertebra which it was necessary to remove in order to remove a protrusion of the lumbosacral disk.

In spite of our ability to diagnose the lesion accurately in some cases, it seems to me that it is the better part of wisdom to employ a contrast medium in almost a routine way as a safeguard against overlooking multiple lesions, which we found in 12 per cent of cases in which radiopaque oil was used,⁵ and to enable the surgeon to perform as short a laminectomy as possible (figs. 1 and 2). A shorter laminectomy naturally means a shorter operation, a shorter period of anesthesia and, to a certain extent, a shorter convalescence.

Just as there are some cases which are so typical that a clinical diagnosis of protruded intervertebral disk can be made and operation advised without visualization of the lesion by a contrast medium, there are occasional patients for whom we have advised and performed laminectomy for protruded intervertebral disk in spite of the failure of radiopaque oil to disclose an intraspinal lesion. I have operated on eleven such patients up to Nov. 22, 1938.⁶ It was, in fact, the experience gained with these patients that led Dr. Craig and me to operate, without the employment of a contrast medium, on other patients having typical cases of protruded disk.

The following two reports will illustrate the points (1) of negative roentgenologic study made with radiopaque oil in the presence of a protruded intervertebral disk in the lumbosacral articulation and (2) a direct exploration for protruded disk on the basis of a clinical diagnosis.

REPORT OF CASES

CASE 1.—A woman aged 48 registered at the clinic Sept. 20, 1938, with a history of intractable left sciatic pain. She had sustained a slight injury to the back at the age of 12 or 13. Between the ages of 14 and 47 she had experienced many episodes of what was called "lumbago." The attacks of "lumbago" were usually precipitated by unusual exercise. In April 1938 she made a misstep and felt something give way in her back. It was necessary for her to sit down immediately; then she noticed an inability to cross her legs. After ten minutes she tried to get up, but she screamed with an excruciating pain in the back in the left sacro-iliac region. For four days she was unable to void urine or move her bowels. After a few days the pain began to radiate down the posterior surface of the left thigh. This pain was exaggerated by coughing and sneezing. After two weeks' time the pain began to subside and she was fairly comfortable until ten weeks prior to admission to the clinic, when she noticed gradually increasing pain in the left thigh with tendency of the pain to radiate to the left groin. The pain was so severe that it interfered with sleep, and the usual methods of treatment failed to give relief.

On examination a positive Lasègue's sign was elicited on the left side. Reflexes of both achilles tendons were markedly diminished. There was weakness of extension of the left toes and definite tenderness along the course of the left sciatic nerve. Roentgenologic examination of the spinal column revealed a narrowing of the space between the bodies of the fifth lumbar and first sacral vertebrae. Diagnostic spinal puncture revealed a total protein content of 40 mg. per hundred cubic centimeters of cerebrospinal fluid, with normal hydrodynamics. Roentgenologic examination of the spinal canal after introduction of 5 cc. of radiopaque oil did not disclose any intraspinal lesion. The patient was treated by Buck's extension of both extremities, a lumbar sling and diathermy. She was

Fig. 2.—Hemilaminectomy in the lumbar region for removal of unilateral protrusion of an intervertebral disk. Only a portion of the lamina on the left side was removed in this instance.

closely observed but failed to obtain any benefit. In spite of the negative results yielded by roentgenologic examination with radiopaque oil Dr. Ghormley, Dr. Walsh and I felt that the patient might have a protruded disk. Exploratory laminectomy for such a lesion was advised with the understanding that if a protruded disk was not found the patient was to undergo operation for bone graft, to be performed by Dr. Ghormley.

October 10 hemilaminectomy of the left lamina of the fifth lumbar vertebra was performed. As soon as this piece of bone had been removed, a marked thickening of the ligamentum flavum between the fifth lumbar and first sacral vertebrae was

4. Craig, W. McK.: Personal communication to the author.

5. Camp, J. D.: Unpublished data.

6. Love, J. G.: Protruded Intervertebral Disk (Fibrocartilage), to be published.

observed. When the left half of the ligamentum flavum was resected, characteristic edema of the nerve root was observed and when the enlarged nerve root was retracted a large unilateral protrusion of the disk between the fifth lumbar vertebra and the first sacral vertebra was uncovered. The protrusion was still partially maintained by the posterior longitudinal ligament and, when this ligament was incised, two large fragments of fibrocartilage escaped.

Fig. 3.—Two fragments of fibrocartilage which constituted the protrusion in case 1.

The removal of these fragments (fig. 3) restored the spinal canal to normal size and shape and removed pressure from the edematous nerve root. The radiopaque oil was then removed from the subarachnoid space and the wound was closed in layers.

Dr. Ghormley was present at the operation and agreed with me that sufficient cause for the patient's symptoms had been

found and removed and that operation for bone graft was unnecessary. The patient's convalescence was uneventful except for the flare-up of an old subdeltoid bursitis. She was dismissed from our care October 27, at which time her wound was completely healed and she was free of her low back and sciatic pain.

CASE 2.—A man aged 35 came to the clinic with the chief complaint of pain in the left area of distribution of the sciatic nerve. Four years prior to admission to the clinic, while stooping over, he felt a snap in his back, immediately followed by severe pain in the lower part. Three years later severe aching and shooting pain developed in the left sciatic distribution. The pain was worse at night and often was relieved by getting out of bed and walking about. The sciatic pain was aggravated by coughing, sneezing and bending the head forward. For three months there had been constant low back and sciatic pain and the patient was unable to work. He walked with a distinct limp and a list. The left achilles tendon reflex was absent. There was a total protein content of 90 mg. per hundred cubic centimeters of cerebrospinal fluid. The original roentgenogram disclosed narrowing of the space between the fifth lumbar and first sacral vertebrae. Motions of the spinal column were markedly limited and Kernig's and Lasègue's signs were positive on the left. Because of the classic history and signs, the patient was operated on for a protruded intervertebral disk without the use of a contrast medium. The spinous process and the laminae of the fifth lumbar vertebra were removed. A large protrusion on the left of the disk between the fifth lumbar and the first sacral vertebrae was removed with complete relief of the patient's symptoms.

If the neurosurgeon undertakes to perform laminectomy for protruded lumbar disk without a previous demonstration of an intraspinal defect as outlined by the contrast medium, or if laminectomy is done after a study with radiopaque oil in which results were negative, the patient should be told of the possibility of an exploratory operation which may show nothing. However, in the light of our experience, a clinical diagnosis can be made with a degree of accuracy that is far above that of other commonly made diagnoses.

Before undertaking such an operation, it is essential to know what disks are most likely to be involved and it is well to bear in mind that the lesion is not infrequently multiple (10 per cent of all lesions were multiple in the series in which operation was performed). Of 300 patients operated on, fifteen suffered disk protrusions in the cervical or thoracic region of the spinal canal. I do not believe a neurosurgeon is justified

in operating for a cervical or thoracic protrusion without first obtaining a roentgenologic demonstration of the suspected lesion with a contrast medium, unless there is a definite sensory level, which is always sufficient to justify laminectomy for an intraspinal lesion. However, since 96 per cent of all protrusions in the aforementioned 300 cases occurred at the third, fourth or fifth lumbar vertebral interspace, a direct operation for a lumbar protrusion based on a careful analysis of the observations should not often fail to disclose the lesion, and since in 84 per cent of the 300 cases referred to the protrusions occurred at the fourth or fifth lumbar interspace, the disks at these two interspaces should be exposed first. A removal of the laminae of the fifth lumbar vertebra and a resection of the fourth and fifth lumbar ligamenta flava will result in adequate exposure. If there is a protruded disk, its presence usually will be signalized by a marked thickening of the ligamentum flavum at that particular interspace (fig. 4). In a consecutive series of 175 cases of protruded disk, a note was made on the surgical cards of 155 cases that there was a definite, abnormal thickening or hypertrophy of the contiguous ligamentum flavum. In our earlier cases we came to look on the edema of the involved nerve root as the sentinel which led to detection of the protruded disk.⁷ In the light of subsequent experience we have been warned, and usually of the site, of the protrusion by the thickening of the ligamentum flavum even before the edematous nerve root can be seen.⁸

But the yellow ligament which bridges the space between the laminae of adjacent vertebrae is by no means always thickened. It may be normal in thick-

Fig. 4.—How the protruded part of an intervertebral disk was removed without the performance of laminectomy. This was the second instance in which the protrusion of the disk was exposed and removed after the resection of a very thick ligamentum flavum without the resection of any portion of the laminae of the adjoining vertebra: a, resection of the hypertrophied portion of ligamentum flavum; b, exposure of the protruded intervertebral disk; c, the spinal canal restored to normal after the removal of the protruded fragments of the disk.

ness; in a few cases I have seen it thinned as if it had been eroded by the protruded fragments of disk substance. In one case I found that a long fragment of

mentum flavum, much as a straw has been known to perforate a wood post during a tornado.⁹

The important point to remember about the ligamentum flavum is that although it may be of sufficient size to compress the nerve roots, causing intractable pain, this phenomenon without an associated protrusion of the disk is rare. In operating on 300 patients who had proved protruded disk, we have encountered only twelve cases of hypertrophy of the ligamentum flavum without an associated disk protrusion. Whenever a hypertrophied ligament is found, a diligent search should be made for protrusion of the underlying disk. The following case report is illustrative:

CASE 3.—A man aged 40 had had recurrent attacks of lumbago for twenty-four years. The attacks would occur once or twice a year and usually necessitated the patient's remaining in bed for a week or ten days. For ten years he had suffered a constant dull, aching pain in the lower part of the back. This pain was aggravated by motion. At no time was there any sciatic projection of the pain. Eight months prior to operation the patient experienced a sharp pain in the right lumbar region while bending over to pick up an object from the floor. This sharp pain in the right lumbar region persisted until the time of operation. At epidural injection there was a marked exaggeration of the severe, sharp pain in the lower part of the back, but at no time was there any extension of the pain into the hips or legs. The total protein content of the spinal fluid was 120 mg. per hundred cubic centimeters of cerebrospinal fluid. Roentgenologic study aided by radiopaque oil revealed a persistent defect opposite the interspace between the eleventh and twelfth thoracic vertebrae which was interpreted as a classic defect for a hypertrophied ligament without disk protrusion. At the time of laminectomy, a hypertrophied ligamentum flavum and a protrusion of the underlying disk at the eleventh thoracic interspace were removed. The patient has obtained complete relief from his backache since operation and he states that he now feels better than he has felt for many years. It is interesting to observe that this patient had suffered a marked narrowing of the space between the fifth lumbar and first sacral vertebrae with some hypertrophic changes yet at no time did he experience sciatic pain. Clinically, an intraspinal lesion occurring in the lower thoracic region was considered to be a diagnosis much more likely to be proved at operation as a cause of this patient's symptoms than the diagnosis of a lesion at the lumbosacral articulation, where a definite abnormality was seen on the usual roentgenologic examination.

TREATMENT OF PROTRUDED INTERVERTEBRAL DISKS

When the presence of a protruded disk has been diagnosed, a decision as to the proper treatment must be reached. If the patient's symptoms are mild and do not interfere to any great extent with his usual activities, some one of the more common therapeutic measures may be employed. However, the presence of the lesion must not be disregarded or passed over lightly, because another slight injury to the back may result in further protrusion of the involved disk, with sufficient narrowing of the spinal canal to produce paralysis of the legs. Case 4 emphasizes this point:

CASE 4.—A man aged 38 had for twenty-one years experienced a yearly recurrence of pain in the lower part of the back. The first attack had occurred following the lifting of a heavy sack, and each subsequent attack followed unusual stress, such as the lifting of heavy objects. One week prior to admission there was a sudden onset of severe pain in the lower part of the back, with bilateral sciatic extension, occasioned by the patient's efforts while cranking a tractor. Three days before admission a "dead feeling" developed in the right leg and there was gradually increasing motor weakness in the

right lower extremity. For two days he had suffered incontinence of both bladder and bowel. The patient had noticed the development of a cough during the same day on which he had injured his back while cranking the tractor.

The neurologic examination showed a reduction of severe degree in motor power of the right leg. The achilles tendon reflexes of both extremities were absent. There was anesthesia in the cutaneous areas supplied by the fifth lumbar and first sacral nerves on the right. A diagnostic spinal puncture in the fifth lumbar interspace was performed and a specimen of cerebrospinal fluid was removed which contained 160 mg. of total protein per hundred cubic centimeters and 2 lymphocytes and 2 polymorphonuclear leukocytes per cubic millimeter of cerebrospinal fluid. The initial pressure of the cerebrospinal fluid was 20 cm. of water. The Queckenstedt test could not be performed because trial of it precipitated a paroxysm of coughing referable to the fact that the patient had an infection in the upper part of the respiratory tract and accurate readings could not be taken.

By the time the patient was considered to be in condition for operation (approximately two weeks after admission) both legs were paralyzed. A differential diagnostic spinal puncture was performed in order to localize the lumbar intraspinal lesion, which, because of the history, was suspected of being a protruded intervertebral disk. A spinal puncture needle was introduced into the twelfth thoracic interspace and clear fluid was obtained without evidence of spinal subarachnoid block. Another needle was introduced into the first lumbar interspace, once more with normal results. At the fifth lumbar interspace, yellow fluid was obtained with a complete spinal subarachnoid block. This fluid on examination revealed 1,200 mg. total protein per hundred cubic centimeters of fluid. Laminectomy was then performed under paravertebral anesthesia and a large fragment of a protruded disk was removed at the site of the fourth lumbar interspace.

Two months after this operation there was a marked improvement in the patient's condition. He was able to walk without aid, whereas it had been possible for him to walk only with the aid of crutches on leaving the hospital; and he volunteered the information that his back felt better than it had felt for five years and that there was no pain or soreness in his back or legs.

If the patient is very uncomfortable or is experiencing enough trouble to warrant bed treatment for two weeks, surgical treatment of the lesion should be advised. The surgical treatment consists of the removal of the protruded portion of the involved disk through a laminectomy wound.

CASE 5.—A man aged 35 had felt pain in the back and left leg intermittently for the past twelve years, occasioned by the patient's sustaining an injury. It was alleged that he had suffered fracture of the fourth and fifth lumbar vertebrae. There was no paralysis at the time of injury. The pain was exaggerated by coughing, sneezing and activity. Pain did not disappear during rest. The left achilles tendon reflex was slightly diminished. Roentgenologic examination of the spinal column produced negative results. The cerebrospinal fluid had a total protein content of 60 mg. per hundred cubic centimeters of fluid. Roentgenologic examination with radiopaque oil revealed an extradural defect on the left, opposite the lumbosacral articulation. Laminectomy, with resection of the hypertrophied ligamentum flavum and removal of a large protrusion of the disk between the fifth lumbar and first sacral vertebrae, was done. The patient made an uneventful convalescence. Postoperative neurologic examination yielded negative results. Complete relief of pain was achieved.

This is an operation which should not be undertaken unless the surgeon has had considerable experience with intraspinal surgery. The lesions are at times small and can be overlooked easily. The cauda equina must be handled only with extreme care, and hemostasis must be very accurate or a postoperative hematoma may nullify the relief that should ensue following the removal of the protruded disk.

9. Love, J. G.: Intractable Low Back and Sciatic Pain Due to Protruded Intervertebral Disks: Diagnosis and Treatment, *Minnesota Med.* 21: 832-838 (Dec.) 1938.

If radiopaque oil is used to localize the lesion, it should be injected into the subarachnoid space in the lumbar segment and the roentgenologic examination should be carried out on the day of operation. It has been our experience that injection of radiopaque oil in the presence of a space-occupying intraspinal lesion is much more likely to be followed by an exaggeration of the patient's symptoms than it would be if there were no intraspinal lesion. The larger the lesion, the greater the compression of the subarachnoid structure and the greater the chance for exaggeration of previous symptoms will be. This fact is not surprising, for I have noted that even a diagnostic spinal puncture in the presence of a large intraspinal tumor will result in the development of marked neurologic signs (and even paraplegia) which were not present prior to the withdrawal of cerebrospinal fluid from the region about the tumor.

If a protruded disk has been demonstrated and operation is to follow, the patient should be prepared for laminectomy. If the roentgenologic study with radiopaque oil is negative and if the other signs are not sufficient to warrant an exploratory laminectomy, the patient should be kept in bed overnight and allowed to leave the hospital the next morning, unless he was previously a hospitalized patient receiving other treatment.

Radiopaque oil is, of course, a foreign substance, and it is eliminated very slowly from the subarachnoid space.¹⁰ It should therefore be used only in carefully selected cases. An intraspinal inflammatory lesion is a definite contraindication to its use.

More recently we have employed air¹¹ in the subarachnoid space as an aid to roentgenologic localization of protruded disks (fig. 5 *a* and *b*). When a definite defect can be shown, air is an excellent contrast medium, but the accuracy achieved by this method in our hands has not approached that resulting from the use of radiopaque oil.

The operation for the removal of a protruded disk is laminectomy. The laminectomy should be as short as possible, yet adequate to permit a satisfactory exposure of the protruded disk. The removal of one pair of laminae will ordinarily provide adequate exposure. In many cases I perform what I call a "partial laminectomy" (see fig. 1); that is, a removal of the edges of the laminae above and below the interspace at which the protrusion has occurred. The articular facets always should be preserved. On one occasion I was able to remove a protruded disk without the removal of any bone. Resection of the hypertrophied ligamentum flavum permitted exposure and removal of the underlying protrusion with complete relief of nerve root pressure and the intractable sciatic pain.

CASE 6.—A man aged 54 registered at the clinic Nov. 28, 1938, at which time he came seeking relief of intractable left sciatic pain of four months' duration. He had experienced onset of the pain in July 1938 while on a motor trip. The first symptom to appear was a difficulty in sitting. He noted that he had to rest first on one buttock and then on the other. There was a dull aching pain in the left lower lumbar region, which had become progressively worse. He had been kept in bed for several days in August, and he began to limp in September. He had discovered that the limp minimized the pain in the back. In October the pain was projected along

the left sciatic nerve. The patient volunteered the information that pain was worse while he was in the sitting position and when he turned in bed. The pain was exaggerated by coughing and sneezing. The usual conservative treatment had failed to give relief.

Examination disclosed that the patient walked with a distinct left-sided limp. There was tenderness over the lumbosacral articulation and along the left sciatic nerve. The straight leg-raising test for the left extremity gave a positive reaction. The left achilles tendon reflex was somewhat diminished over that of the right. Roentgenologic examination of the spine disclosed a partial sacralization of the fifth lumbar vertebra with a definite narrowing of the fourth lumbar interspace. A spinal puncture by the patient's local physician had revealed a total protein content of 60 mg. per hundred cubic centimeters of cerebrospinal fluid. A combined diagnostic lumbar puncture and spinogram (air injection into the spinal subarachnoid space) were made at the clinic. After introduction of the lumbar puncture needle into the first lumbar interspace the air was injected under slight pressure, and 45 cc. of air was used to replace 40 cc. of fluid. When the fluid in the lumbar sac had been displaced by air, roentgenograms disclosed a left antero-lateral defect opposite the fourth lumbar space. A diagnosis of protruded intervertebral disk was made and operation was advised.

December 1 a classic protrusion of the fourth lumbar disk was removed without the performance of laminectomy. The

operation was planned as a left hemilaminectomy, but when the fourth interspace was exposed the

Fig. 5.—*a*, Anteroposterior view of the lumbar portion of the spinal column after the cerebrospinal fluid had been replaced with air. The point of the arrow indicates the defect in the air column caused by a protruded intervertebral disk; *b*, drawing to indicate the defect seen in the roentgenogram.

ligamentum flavum was found to be unusually thick. When the left half of the ligament was resected characteristic edema of the underlying nerve root, with posterior displacement such as is seen with an underlying protrusion of the disk, was noted (see fig. 4). The involved nerve root was retracted and a large fragment of fibrocartilage was removed from the disk. This operation relieved the cauda equina of pressure and the wound was closed without removal of any bone.

POSTOPERATIVE TREATMENT

The care of patients on whom laminectomy has been performed for the removal of a disk protrusion has gradually evolved into a very simple system. Since but little bone is removed and since the incision in the skin and fascia is short and the heavy erector spinae muscles are reflected subperiosteally, there is little that could have an adverse effect on such a wound if an accurate anatomic closure has been effected. As has been stated, no bone grafting or fusing is done, therefore there is no need for splinting, casting or even keeping the patient quiet in bed. Instead, these patients are left to their own inclinations, so to speak, when they are placed in their beds after leaving the operating room, and they are encouraged to move their toes, feet and legs as soon as they recover from the effects protruded disk had completely perforated the liga-

of anesthesia. After every laminectomy the ability of the patient to move his toes should be observed and charted frequently during the first six hours after operation. After that his power should be determined several times a day for the first few days. If there is weakness that was not present prior to operation, hemorrhage should be suspected and the wound should be opened to exclude such a possibility. We have encountered only one postoperative hemorrhage in 300 laminectomies performed for the condition of protruded intervertebral disk. There has been one postoperative death in the series.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. SPURLING AND BRADFORD, DRs.
CHAMBERLAIN AND YOUNG, DR. CAMP
AND DR. LOVE

DR. WILLIAM JASON MIXTER, Boston: I will accept Dr. Love's change in nomenclature. The term "ruptured intervertebral disk" was used at first because it was not realized that in some of these cases the annulus was not ruptured but was protruded without being ruptured. I must disagree with Drs. Spurling and Bradford and say that the annulus is involved in the process as well as the nucleus pulposus, and so the term "extrusion of the nucleus pulposus" is not a good one. The differentiation between the fourth and the fifth disk, in my hands, has been rather more difficult than Dr. Spurling has indicated. I agree that air will show a certain percentage of extrusions. I doubt whether it will show small defects which will be shown by iodized oil; I doubt whether it will show some of the larger and more diffuse defects which will be shown by iodized oil. Air can be used in a certain number of cases which lie on the borderline in which one would not be willing to use iodized oil. If one gets a positive effect with the injection of air iodized oil is unnecessary, the dural sac will not have to be opened and it will make the surgeon's job a shorter and an easier one. But I am afraid that one has to admit a considerable percentage of error on the negative side. I believe that one is justified, as both Dr. Love and Dr. Spurling said, in operating in a certain number of cases in which there are classic signs without the use of a contrast medium. The greatest difficulty is in cases in which the signs are not classic, and here I come to the point that there are many patients with low back pain, possibly with sciatica, who should not under any circumstances have iodized oil injected because, as Dr. Love has already stated, a very large percentage of patients with sciatica and low back pain will recover spontaneously. It is only by picking out severe, intractable cases extending over months that one can eliminate the promiscuous and pernicious use of iodized oil in the spinal canal. The use of iodized oil in the spinal canal should be carried out only in the clinic when the patient is to be operated on. It is unfair to the roentgenologist who will have to examine that patient in the operative clinic, and it is unfair to the surgeon who is going to operate on the patient to use iodized oil, run it around in the spinal canal and then send the patient down to the ultimate operative clinic. One does not like to use iodized oil if one can help it, but the subject was developed on the basis of the use of iodized oil. We never would have gotten anywhere with protrusion of the intervertebral disk except by the use of that drug.

DR. CLAUDE MOORE, Washington, D. C.: As Dr. Mixter said, it is not fair to throw the burden of the responsibility of the diagnosis on the roentgenologist without definite indications. I would like to call attention again to the very definite and clear-cut pathologic changes demonstrated on the films shown by Dr. Camp and Dr. Love using iodized oil as compared with those of Drs. Chamberlain and Young using air. I admit that the use of air is an excellent preliminary procedure, but when the patient is going on to neurosurgery the added risk of iodized oil and colloidal thorium dioxide injected into the spinal canal is only slight compared to a major neurosurgical operation.

DR. L. H. GARLAND, San Francisco: Dr. Chamberlain has again demonstrated the value of air myelography in the diagnosis of large space-occupying lesions of the spinal canal (especially with thin patients and perfect radiographic technic), and

Dr. Camp has pointed out the usefulness of the lateral projection for the diagnosis of hypertrophy of the ligamentum flavum. In my experience at the San Francisco Hospital I have found satisfactory diagnostic results with air in only about one tenth of the cases; in the remainder, iodized oil had to be used, either because preliminary air films were inconclusive or because the patient was so thick that we did not deem it advisable to use air. Now, Dr. Chamberlain uses air because he thinks that iodized oil, if left in the cerebrospinal system, may produce late, harmful changes. Dr. Mixter stated that if it gets into the skull it may produce intractable headaches. It seems to me that neither of these opinions is correct. We have made careful x-ray and clinical follow-up studies of twenty-five patients who had iodized oil injected into the spinal canals from one to fourteen years prior to the check-up, in amounts varying from 2 to 5 cc. (and in one remarkable case 10 cc.). In not one of these twenty-five cases is there any subjective or objective evidence to indicate damage to the central nervous system. We did an autopsy on one patient; it revealed the usual leptomeningeal thickening about some of the collections of iodized oil but absolutely no neural tissue changes. About two thirds of the patients had small intracranial collections of iodized oil in and about the basal cisternae without having any headache or other symptoms. As long as the roentgenologist or clinician knows that this intracranial oil is asymptomatic, and apparently harmless, he will not be disturbed by finding it. I do not advocate the indiscriminate intraspinal injections of any substance, gaseous or oleaginous, but I do believe that, in selected cases, the use of small amounts of fresh iodized oil is harmless. Its diagnostic value is far greater than that of air.

DR. J. DANIEL WILLEMS, Chicago: The general tone of conservatism of these papers has been gratifying. I am in a different position from the speakers; I am placed in somewhat of a referee position. These patients come to me after they have been operated on. I cannot talk in figures of 300 but I have several dozen by this time, patients who have been operated on in some of the best clinics in this country; they come back to me with all sorts of complications, weeks later and months later. Most of them are workmen; they should return to work, and I cannot for the life of me get them back to work. Of all the complications, the worst is the presence of iodized oil as shown by the x-ray film. I would make a plea for conservatism, especially in the use of iodized oil such as can be shown in x-ray films later.

DR. R. GLEN SPURLING, Louisville, Ky.: I proposed on two occasions before this Association the use of iodized oil for diagnosis of these intraspinal lesions, and I have used it without any fear of dangerous reaction or permanent disabling effects. However, I have always had more or less difficulty convincing orthopedic surgeons and others that iodized oil is an innocuous substance, and we know it is not entirely innocuous because after the immediate reactions there is always inflammation. I had this brought to my mind forcibly three months ago by a doctor who saw a relative of his with one of these lesions. I told him that I felt reasonably sure that there was a herniated nucleus pulposus at the fifth lumbar interspace. He said "You can operate, but you can't inject lipiodol." I think that represents the attitude of many in the profession regarding this drug, and if that argument could be eliminated from the whole picture of disease of the intervertebral disk some progress in the final solution of the problem would have been made. I do believe that with more mature consideration of the neurologic aspects, both subjective and objective, we can arrive at a definite, accurate diagnosis in a large percentage of cases that require surgery. I do not doubt that there are many acute cases in which localization cannot be made, but in my opinion most of these patients should not be treated surgically. It is only intractable cases that require surgery, of which I was speaking in my paper. As regards the terminology, I believe that in those cases in which there is a frank mass present beneath the posterior longitudinal ligament it is usually composed chiefly of nuclear material with fragments of annulus fibrosus attached to it. Our surgical specimens have been carefully examined grossly and histologically, and they have shown predominantly nucleus pulposus. Furthermore, when we remove one of these masses and inspect

the operative site carefully we see that the protrusion is immediately relieved, that the gaping edges of the posterior longitudinal ligament fall back together, and there is very little to tell the story of the former disruption. That, to me, is further argument that the presenting lesion is composed chiefly of nuclear material. Furthermore, that would bear out our conception of the symptomatology, since we feel that the low back pain is due to stimulation of the sensory nerve endings supplied by the recurrent branches of those nerves, and the root pain is due to a pressing mass beneath or outside the posterior longitudinal ligament which has impinged on one of the nerves at its point of fixation.

DR. W. EDWARD CHAMBERLAIN, Philadelphia: Our use of oxygen instead of air as the contrast medium for myelography is due entirely to the fact that oxygen disappears from the lumbocaudal sac (is absorbed) more rapidly than air. After the use of air the patient's sacrum must be kept higher than the foramen magnum for at least twenty-four hours, whereas after the introduction of oxygen, three or four hours of the special posture seems to suffice. However, Dr. Adson called my attention yesterday to an effective way of hastening the absorption of ordinary air. He simply has his patient breathe pure oxygen through the new Loveless mask. This reduces the nitrogen tension in the blood and brings the rate of absorption of ordinary air up to about that of oxygen. I wish to commend Dr. Spurling for his emphasis on the clinical neurologic study. There has been too much emphasis on studies with contrast mediums to the exclusion of clinical methods of examination. Just as too many radiologists have adopted the attitude that oxygen myelography is too difficult and iodized oil cannot be supplanted, too many clinicians have adopted a defeatist attitude toward the neurologic examination. In our many contacts with Dr. Fay and his associates in the Department of Neurology and Neurosurgery at Temple, we have learned to appreciate the value of the clinical neurologic examination as stressed by Dr. Spurling. When these intervertebral disk protrusions were first recognized, I think most of us took it for granted that symptoms from such a cause could be relied on to be either progressive or at least constant. But now we know that, as stressed by Dr. Mixter and again by Dr. Love, 80 per cent of patients with disk lesions manifest a distinctly intermittent symptomatology. This intermittent feature has aroused our special interest, for it is so marked as to suggest that the mechanical factor, the actual disk protrusion itself, must also be intermittent. That this may be the case is suggested by our recent demonstration, in quite a series of cases, that flexion of the spine tends to "withdraw" disk material from the spinal canal, while extension tends to produce or emphasize protrusion. In one of our surgical cases Dr. Fay demonstrated, on the operating table, this "withdrawal" and recurrence of the disk protrusion with flexion and extension of the spine.

DR. JOHN D. CAMP, Rochester, Minn.: I do not believe that any of the substances that have been talked about today are ideal substances for this work. Sooner or later somebody is going to perfect a radiopaque substance which can be injected into the subarachnoid space and be eliminated rather rapidly by the spinal fluid. When that time comes I feel that roentgenology will have added another great step forward in the study of many neurologic conditions.

DR. J. GRAFTON LOVE, Rochester, Minn.: Dr. Mixter has warned about the injection of iodized oil, and we have adopted the attitude. We have stopped injecting iodized oil for diagnostic purposes unless the patient has already planned—if the study is positive—to proceed with the operation, preferably the same morning. The injection is made in the operating room, Dr. Camp does his fluoroscopy, then the patient is taken back to the operating room and a laminectomy is performed. Walsh and I have collected, at the time of laminectomy, a number of specimens of fluid, and we have been able to show that there is an increase in lymphocytes following injection. They reach their height within one or two hours and subside in from twenty-four to forty-eight hours, and the iodized oil, if removed immediately, appears as it did when it came out of the ampule, whereas if it is removed the next day it has the appearance of clabber or sour milk, and it is during that period that there

are irritating properties to the iodized oil, and if there is a nerve compressed the symptoms are apt to be more marked. The same thing is seen in spinal tumor; the symptoms may be remarkably exaggerated following removal of a sample of fluid. So if there is an intraspinal injection, operation should not be delayed. In some of my earliest cases I purposely left the iodized oil in and did not open the dural sac because of the marked extradural bleeding which sometimes occurs. Some of my first cases were so troublesome that I wanted to maintain the hydrostatic effect in the caudal dural sac. Certainly, the large number of patients who had been chronic invalids and had been incapacitated for any type of work and who were relieved by laminectomy and were out in a short time following use of iodized oil is some proof. The patients we deal with are incapacitated, patients who have been in bed for six months, patients who have had various operations, who have had bone grafts, who have had manipulations under anesthesia, who have been in bilateral spica casts for three to six months. A protrusion of the fourth lumbar disk cannot be differentiated from a protrusion of the fifth disk. One can show a protrusion of any of the lumbar disks with the same clinical and neurologic manifestations. There is an important point about the intermittence of symptoms that has intrigued all of us. Why will these patients get relief? my orthopedic colleagues ask me. In the past, we have brought about fusion in some of these cases, seeing the number of protruded intervertebral disks. It is my feeling that, if the protrusion is at the lumbar sacral disk and a massive bone graft is applied, the patient may be cured. If a sacro-iliac joint is fused it would have no effect on the patient. I think that as time goes on some of these patients cure themselves, the edema subsides and the tissue contracts, because this is not neoplastic.

THE EFFECTS OF OBSTETRIC ANALGESIA ON THE NEWBORN INFANT

JACOB KOTZ, M.D.

AND

MORTON S. KAUFMAN, M.D.

WASHINGTON, D. C.

The effect of obstetric analgesia on the newborn infant has been the subject of considerable discussion during the past few years both in medical literature

Chart 1.—Average weight in complete series: solid line normal, dotted line McCormick modification of Gwathmey technic, dashes paraldehyde, dots and dashes pentobarbital sodium.

and in the lay press. Analgesia has been accused of depressing the vital functions during the first few days of life, of causing permanent damage to the cerebral centers and of increasing fetal mortality.

Since obstetric analgesia is becoming so widely used, it is important to determine whether such is the case.

From the Department of Obstetrics and Gynecology, George Washington University School of Medicine.

Read before the Section on Obstetrics and Gynecology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

The group in which the McCormick technic of analgesia was used is presented through the courtesy of Dr. Prentiss Wilson, Washington, D. C.

A comparative study of large groups of newborn infants under the same environmental conditions, some of whose mothers received analgesia while those of others did not, would appear to be the logical method of approach to this problem. If obstetric analgesia is harmful to the infant, it should be reflected in the mortality rate

Chart 2.—Average weight in paired series: solid line normal, broken line paraldehyde.

and the records of the vital functions during the first ten days of life. We have completed such a study and herewith submit a summary of our observations.

METHODS

Eight hundred consecutive babies born of mothers delivered by the vaginal route in private practice were selected for this study; in 500 instances the mother received paraldehyde either alone or in combination with some other drug, in 100 instances she was treated by the McCormick modification of the Gwathmey technic and in 100 she received pentobarbital sodium and scopolamine. The babies of 100 mothers who received no analgesia were used as controls.

In these groups the following factors were studied: (1) the mortality rate, (2) the initial loss of weight, (3) the rate of gain for the first ten days of life, (4) the temperature curve for the first ten days of life and (5) the pulse and respiration curve for the first ten

Chart 3.—Average temperature in complete series: lines as in chart 1.

days of life. Also due consideration was given to the duration of labor, the type of delivery, the dosage of the analgesia used and its effect on the subsequent clinical course of the infants after birth.

One hundred additional cases were selected for a more detailed study. In fifty the mother received paraldehyde analgesia. In each of these cases the infant was matched with another child, born on the same day and of approximately the same birth weight but whose mother received no analgesia. The two babies were

fed identical formulas and the environmental conditions were the same. In these cases the temperature, pulse and respiratory rates were recorded every four hours and the weight was checked twice a day for the first three days of life.

The time interval between delivery and the initial respiration was checked with a stopwatch on 100 paraldehyde babies and 100 control babies.

Dosage of Analgesia.—The average dosage of paraldehyde was 17.5 drachms (66 cc.) given with an average of $1\frac{1}{60}$ grain (0.012 Gm.) of morphine sulfate. The usual initial dose was from 6 to 8 drachms (23 to 31 cc.) of paraldehyde by rectum and one sixth or one fourth grain (0.011 or 0.016 Gm.) of morphine hypodermically, the paraldehyde being repeated in 3 or 4 drachm (12 or 15.5 cc.) doses as often as necessary. The largest total dose given was 38 drachms (142.5 cc.) of paraldehyde and one fourth grain of morphine. It is apparent and we wish to emphasize the fact that in this series of cases large doses of analgesia were used. If analgesia has an effect on the child, such effects would certainly be demonstrable in this group.

In the group of mothers treated by the McCormick technic, the average amount given was 1.53 doses of the mixture and 4.99 grains (0.32 Gm.) of pentobarbital sodium.

In the group receiving pentobarbital sodium and scopolamine the average total dose was 6.78 grains (0.44 Gm.) of pentobarbital sodium and $\frac{1}{200}$ grain (0.0003 Gm.) of scopolamine.

Chart 4.—Average temperature in paired series: solid line normal, broken line paraldehyde.

RESULTS

Duration of Labor.—The average duration of labor in this series of cases was seventeen and one-half hours for primiparas and thirteen and one-half hours for multiparas. This is corroborative of the observations made by Rosenfield and Davidoff,¹ Colvin and Bartholomew² and Kane and Roth³ and definitely demonstrates that labor is not prolonged by the use of any of these types of analgesia.

Incidence of Operative Delivery.—It has long been recognized that any factor which increases the incidence of operative delivery adds to the fetal risk. The type of delivery in the various series of cases is summarized in table 1. The high incidence of forceps is due to the fact that we use prophylactic forceps as a routine and do not consider it an increase in operative intervention.

Effect of Analgesia on Fetal Mortality Rate.—In the 500 cases in which paraldehyde analgesia had been given there were eleven fetal or neonatal deaths. This represents a gross mortality rate of 2.2 per cent. Table 2

1. Rosenfield, H. H., and Davidoff, R. B.: Paraldehyde as a Factor in Painless Labor, Surg., Gynec. & Obst. 60: 235-238 (Feb.) 1935.
2. Colvin, E. D., and Bartholomew, R. A.: Advantages of Paraldehyde and Basic Amnesic Agent in Obstetrics, J. A. M. A. 104: 362-367 (Feb. 2) 1935.
3. Kane, H. F., and Roth, G. B.: Use of Paraldehyde in Obtaining Obstetric Analgesia and Amnesia, Am. J. Obst. & Gynec. 29: 366-369 (March) 1935.

lists the cause of death in the individual cases. There were seven instances in which the cause of death could be ascribed definitely to factors other than the analgesia. In the remaining four cases death was attributed to atelectasis. Of these four cases, one mother received only 6 drachms (23 cc.) of paraldehyde and another 10 drachms (38.8 cc.). One mother received 34 drachms (127.5 cc.) of paraldehyde and one sixth grain of morphine in a period of forty-four hours. This infant's urine gave a strong reaction for paraldehyde. If one considers these four deaths to be due to the

TABLE 1.—Types of Delivery

paraldehyde, the fetal mortality rate from the drug is 0.8 per cent. Adair states that in many stillbirths there is no demonstrable lesion at autopsy other than atelectasis. Dr. Choisser,⁴ pathologist of the George Washington Hospital, reports that atelectasis is a common finding in stillbirths but that it is not more frequent in cases in which the mothers have received paraldehyde

ing interval recorded on 100 babies whose mothers received no analgesia. The average intervals in the two groups were 39.5 and 9.8 seconds respectively.

Granting that the initial respiration is slightly delayed, the question still arises "Does this slight delay have any injurious effect on the baby?"

Birth Injuries.—There was only one birth injury in this series of cases: Erb's paralysis developed as the result of traction on the neck exerted to deliver the impacted shoulders. In the follow-up studies of these babies during the past five years there has been no instance of convulsions, mental retardation, spastic paralysis or other evidence of neurologic defects. From these data it seems reasonable to conclude that cerebral injuries in the newborn are due to mechanical factors, usually faulty obstetric manipulation, rather than to the drug given the mother.

MORBIDITY

Pediatricians have repeatedly stated that babies whose mothers are given analgesia during labor are sluggish and drowsy for the first three or four days of life and that they fail to nurse properly and therefore lose more weight and become more dehydrated than babies whose mothers receive no analgesia. This has not been our experience, as the following data will show:

Weight.—The average daily weight changes of the 489 babies whose mothers had paraldehyde, the ninety-

TABLE 2.—Cases of Fetal Death

Case	Dose of Analgesia			Type of Delivery	Weight		Time of Death	Maturity	Autopsy Results
	Duration of Labor, Hours	Paraldehyde, Drachms	Morphine hyde, Sulfate, Grain		Pounds	Ounces			
1	4	12	¼	Breech	2	2	24 hr. post partum	6½ months	Premature
2	Spontaneous	2	0	24 hr. post partum	6½ months	Premature
3	50	26	..	Low forceps	3	12	3d day	7½ months	Anencephalle
4	12	21	..	Low forceps	7	6	24 hr. post partum	Full term	Congenital, hydro-nephrosis, broneho-pneumonia
5	16	14	¼	Breech extraction, forceps to after coming head	4	9	24 hr. post partum	8½ months	Tentorial tear
6	16	9	¼	Breech extraction, forceps to after coming head	6	3	Stillbirth	Full term	Tentorial tear
7	12	14	¼	Low forceps	4	2	Stillbirth	8 months	Congenital fetal edema, erythroblastosis
8	8	10	¼	Low forceps	6	5	24 hr. post partum	Full term	Atelectasis
9	4	6	¼	Low forceps	4	13	24 hr. post partum	8½ months	Atelectasis
10	20	28	¼	Low forceps	5	1	14 hr. post partum	8 months	Premature
11	44	34	¼	Low forceps	8	0	Stillbirth	Full term	Asphyxia, urine positive for paraldehyde

than in those in which no analgesia was given. We can conclude only that the paraldehyde may or may not have been the cause of death, but we feel that in any group as large as this a like percentage of babies will die from atelectasis or unknown causes resulting in atelectasis, regardless of whether analgesia was used or not.

In the group of McCormick babies there were two deaths, representing a gross mortality rate of 2 per cent. One of these babies had hydrocephalus and the other was premature with atelectasis.

In the pentobarbital sodium group there was one neonatal death of a baby with exomphalos, giving a gross mortality of 1 per cent and a corrected mortality of 0.

THE EFFECT OF ANALGESIA ON INITIAL RESPIRATION OF INFANT

In 100 cases in the paraldehyde group the interval between delivery and onset of respiration was determined by a stopwatch and compared to the correspond-

eight babies whose mothers were treated by the McCormick technic and the 100 babies whose mothers had no analgesia are shown in chart 1. The maximum loss of weight was reached on the third day in all groups. Thereafter all the babies gained steadily and at approxi-

TABLE 3.—Percentage of Babies with Temperatures Over 100 F.

	Day Post Partum									
	1st	2d	3d	4th	5th	6th	7th	8th	9th	10th
Normal.....	2	4	4	5	2	2	1	0	1	0
Paraldehyde.....	1.4	2.2	3.6	1.6	1.8	1.4	1	0.4	0.2	0.4
McCormick.....	1	4	2	4	1	1	1	1	1	1
Pentobarbital sodium.....	1	8.3	4.1	8.3	8.3	8.3	2	4.1	4.1	1

mately the same rate. The average total loss of weight on the third day was 4.5 ounces (128 Gm.) in the paraldehyde group, 4.1 ounces (116 Gm.) in the McCormick group and 4.7 ounces (133 Gm.) in the control group. We were surprised to find that the control babies lost more weight than those whose mothers had

4. Choisser, Roger: Personal communication to the authors.

received analgesia. Recently Cole⁵ has published similar observations.

The average daily change of weight of the fifty pairs of babies is shown in chart 2. The average total loss at the end of three days was 1.9 ounces (54 Gm.) in the paraldehyde group and 2.5 ounces (71 Gm.) in the control series. Here again the greater loss of weight of the group without analgesia is striking. Cole believes that this increased loss of weight of the group of spontaneous deliveries without analgesia is due to increased trauma to the fetal head, which causes shock.

TEMPERATURE, PULSE AND RESPIRATION

The average daily temperature of the four series of cases is represented in chart 3. There is no significant difference between the group whose mothers received analgesia and those whose mothers did not.

It is often stated that analgesia results indirectly in dehydration of the infant owing to its disinclination to take fluids. Dehydration is usually accompanied by an elevation in temperature. Analysis of the series of cases reveals that the percentage of babies whose temperature

Chart 5.—Average pulse rate in paired series: solid line normal, broken line paraldehyde.

Chart 6.—Average respiration rate in paired series: solid line normal, broken line paraldehyde.

rose above 100 F. (table 3) was less in the paraldehyde and McCormick groups than in the control series. The largest percentage of babies with elevation of temperature above 100 F. was in the pentobarbital sodium group.

The average daily temperature (chart 4), pulse (chart 5) and respiration rates (chart 6) of the paired series of paraldehyde and control babies showed no significant difference. The temperature ranged between 97.8 and 98.7 F., the pulse rate between 115 and 127 and the respiratory rate between 30 and 40 in the two groups.

In these paired babies the nursing personnel was unable to note any significant differences between the group in appetite, food consumption, degree of dehydration or attitude except that the babies whose mothers had had analgesia were slightly more drowsy for the first twenty-four hours.

CONCLUSIONS

Obstetric analgesia, properly administered, does not increase the infant mortality or morbidity rates above those which occur in a series of infants whose mothers were delivered without analgesia.

ETIOLOGIC FACTORS IN NEONATAL ASPHYXIA

W. C. C. COLE, M.D.

DAVID C. KIMBALL, M.D.

AND

L. E. DANIELS, M.D.

DETROIT

Asphyxia of the newborn infant has assumed an entirely new significance in recent years for two reasons: a greatly modified conception of the inauguration of respiration and the demonstration of the various pathologic changes that may be produced in the central nervous system by anoxia. Until very recently it had always been supposed that the normal baby was born in a state of physiologic apnea and that as the placental circulation ceased to function the accumulation of carbon dioxide in the blood stimulated the respiratory center and caused respiration to begin.

The studies of Snyder and Rosenfeld¹ have caused us to change this conception almost completely. They have shown beyond much question of doubt that the movements of respiration do not start suddenly at the time of birth but occur in regular rhythm during the latter third of intra-uterine life. According to them there is little essential difference between intra-uterine and extra-uterine breathing except that amniotic fluid instead of air enters the lungs in the former and that of course gaseous exchange does not take place. Moreover, once these movements are established they are continuous and not interrupted unless some profound influence is exerted on the fetus. If this conception is correct, the normal infant should take its first extra-uterine breath within a very few seconds after delivery, and a new importance attaches to the baby that is not breathing at birth. It means that any baby who does not breathe within at the most thirty seconds after delivery must be profoundly affected by something, whether it is strangulation, anesthesia, narcosis, or shock as a result of the trauma of labor.

Of even greater importance, however, than this changed conception of the inauguration of respiration has been the demonstration of the devastating pathologic changes produced in the central nervous system when it is deprived of an adequate supply of oxygen for even short periods of time. Yant and his co-workers² have shown experimentally that the cells of the brain are much more sensitive to oxygen want than most of the other cells of the body and that one minute of complete lack of oxygen may be sufficient to cause their death. Courville³ has described similar changes following nitrous oxide asphyxia and in the newborn.

From the Woman's Hospital.

Read before the Section on Obstetrics and Gynecology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

3. Courville, C. B.: Asphyxia as a Consequence of Nitrous Oxide Anesthesia, *Medicine* 15: 129 (May) 1936.

Extensive areas of "devastation necrosis" have been observed in the brains of infants dying a few days after severe asphyxia at birth which are apparently identical with those observed in death from known anoxic states such as nitrous oxide anesthesia, acute alcoholic intoxication and hyperpyrexia. Schreiber⁴ has emphatically brought to our attention the relationship of asphyxia at birth to serious degenerative changes in the brains of older children and has suggested that in many cases excessive sedation of the mother may be the causative factor.

Schreiber's contention that these serious changes are the result of anoxia, frequently resulting from sedatives given to the mother, places a tremendous responsibility on obstetricians who administer such drugs and pediatricians who care for infants after delivery. If it is true that severe degrees of anoxia produce these severe devastating lesions, then is it not possible that lesser degrees of anoxia will produce lesser lesions? It opens

factors which might produce asphyxia were evaluated. Accordingly, we have reviewed the records of 5,000 mothers and babies delivered at the Woman's Hospital in Detroit during the years 1936 and 1937. The data were tabulated according to the punch card method, which permits the recording of a large amount of data in such a way that they may be accurately cross analyzed in any desired combination of circumstances.

The material at the Woman's Hospital is particularly well adapted to this type of study because 55 per cent of the patients were delivered by general practitioners, 33 per cent were delivered by obstetric specialists and 12 per cent were delivered by the resident staff. This provides for a wide variety of methods and skills. Moreover, all social groups and nationalities are well represented.

up a whole new field of speculation with regard to the possible etiology of such conditions as epilepsy, psychopathic personality and lesser degrees of mental inferiority. Certainly the seriousness of these implications calls for an explanation regarding the role of sedatives and anesthetics in the production of neonatal asphyxia and an appraisal of their comparative importance with other factors leading to this state. Certainly asphyxia was a common occurrence before sedatives or anesthetics were ever administered during childbirth. Such factors as prematurity, the age, parity and health of the mother, accidents of labor, the various forms of dystocia, the duration of labor, the use of oxytocics and operative delivery must all be considered.

It occurred to us that a great deal of valuable information might be obtained from the analysis of a large series of deliveries in which as many as possible of the

Chart 1.—Neonatal deaths in relation to degree of asphyxia.

SERIES AS A WHOLE

Table 1 shows the incidence of the various degrees of asphyxia in the entire series. It is necessary to state at this point our method of determining the various degrees of asphyxia. Technically, asphyxia is a decrease in the amount of oxygen in the circulating blood and only indirectly associated with the respiratory movements. It is obviously impossible by present methods to determine the oxygen concentration of the infant's blood at the exact moment

Chart 2.—Relation of cases of immediate spontaneous respiration to those of severe asphyxia when no sedative had been given the mother.

of birth. We chose as the best available criterion the condition of the baby at birth and the duration and amount of resuscitation necessary to establish independent breathing. The methods of resuscitation employed at the Woman's Hospital are the tracheal catheter, car-

4. Schreiber, Frederic: Apnea of the Newborn and Associated Cerebral Injury, J. A. M. A. 111: 1263-1269 (Oct. 1) 1938.

bon dioxide and oxygen inhalations, respiratory stimulants such as coramine and alpha-lobeline, mouth to mouth breathing and artificial respiration. We considered that any baby who required two or more of these methods of resuscitation was severely asphyxiated, particularly when it was noted on the chart that the

Chart 3.—Effect of scopolamine on respiration of infant.

child was in poor condition for several hours or days after birth. If only one method of resuscitation was employed the baby was classified as mildly asphyxiated. If respiration was spontaneous but delayed for more than thirty seconds the baby was classified as "spontaneous delayed." The stillborn group is obvious.

This method of classification is open to certain errors. One obstetrician might employ more resuscitation than another under similar circumstances, and the reverse

Chart 4.—Effect of pentobarbital sodium on respiration of infant.

before this study was contemplated and accordingly are free from any prejudiced influence by the attending physician or the recording nurse. Furthermore, the relationship of neonatal death to the degree of asphyxia shown in chart 1 bears out the point that a reasonably accurate method of classification was developed.

During this same period the incidence of stillbirths in the city of Detroit was 2.5 per cent. Otherwise we have no basis of comparison with results in other clinics, as no similar classification has ever been made.

Chart 1 shows the relationship of the degree of asphyxia to neonatal death (during hospital stay). In the "spontaneous immediate" group the rate was 0.5 per cent. In the "spontaneous delayed" group it was

TABLE 4.—Age of Primiparas

1 per cent, or twice as great. In the "mild asphyxia" group it was 3.5 per cent, or about seven times as great. In the "severe asphyxia" group it was 12.1 per cent, or about twenty-five times as great. This direct relationship is most striking and can hardly help being highly significant.

FETAL FACTORS

The importance of immature development as a factor in asphyxia is shown in table 2. Prematurity undoubtedly is the most important single factor causing stillbirth and severe asphyxia.

The relationship of the size of the baby to the occurrence of asphyxia was studied by dividing the cases into groups for each pound of variation in their birth weight.

The three groups 6-7 pounds, 7-8 pounds and 8-9 pounds, which represent the general average, were essentially the same with about 8 per cent severe asphyxia and 76 per cent spontaneous respiration.

TABLE 5.—Age of Multiparas

	No. of Cases	Percentage			
		Still-born	Severe Asphyxia	Mild Asphyxia	Spontaneous
Under 20 years.....	59	0.0	3.5	6.9	8.6

Over 40 years.....	37	8.1	10.8	8.1	5.4
					70.3

However, the group of the smallest infants, 5-6 pounds, showed 14 per cent severe asphyxia and only 68 per cent spontaneous respiration, while the group made up of the largest, over 9 pounds, showed but 5.5 per cent severe asphyxia and slightly over 80 per cent spontaneous respiration. This gives additional evidence of the importance of mature development in helping to withstand the forces tending to produce asphyxia.

Chart 5.—Effect of ether anesthesia on respiration of infant.

It is important to note that these data were collected from records made before

MATERNAL FACTORS

Certain factors pertaining to the mother show a definite influence on the incidence of asphyxia in the infant: A. *Parity*.—There were 2,578 primiparas and 2,030 multiparas in the series. The incidence of the asphyxia in these two groups is shown in table 3. A decided

Chart 6.—Elective cesarean section at full term with general anesthesia in sixty cases.

increase in asphyxia in the babies of primiparas is evident.

B. *Age of Mother*.—The relationship between the age of the primiparas and multiparas to the incidence of asphyxia in their babies is shown in tables 4 and 5. Among primiparas, then, the incidence of severe asphyxia increases and spontaneous immediate respiration decreases with each advancing age period. In multiparas the opposite of the situation in primiparas occurs; the incidence of severe asphyxia decreases and immediate spontaneous respiration increases with each advancing age period until after 40, when an extreme reversal sets in. The high percentage of stillbirths by women over 40 is especially worthy of note.

C. *Health of Mother*.—Major illness of the mother is one of the very important factors tending to increase asphyxia in the baby, particularly in the case of premature birth. This is shown in tables 6 and 7.

FACTORS OF LABOR

One of the most important factors in the production of asphyxia is the trauma which the baby sustains from the forces of labor. Table 8 shows the influence of the duration of the second stage of labor. An inspection of this table shows very clearly that, with the exception of the first very short period, there is an increase in the incidence of asphyxia and a decrease in spontaneous immediate respiration with each increase in the duration of the second stage of labor. Chart 2 presents in graphic form this relationship. Severe asphyxia increases from a low of 4.6 per cent to a high of 28.6 per cent, and immediate spontaneous breathing decreases from a high of 84.6 per cent to a low of 50 per cent. It would seem clear that there is a direct relationship between the duration of the second stage of labor and the incidence of asphyxia in the baby. The high incidence of stillbirths in the longest two period groups is worthy of note. The somewhat greater incidence of asphyxia in the very short period group sug-

gests that there is increased trauma to the baby in precipitate deliveries. The same relationship exists between the length of the first stage but in a much less pronounced degree. The trauma exerted on the baby during the first stage of labor is from the contracting uterus as contrasted to the direct trauma to the baby's head, as occurs during the second stage.

It will be shown later that the amount of sedative administered to the mother also has a direct relationship to the incidence of asphyxia. It might be argued that as the duration of labor increases the amount of sedative given also increases and that therefore the results shown in the foregoing tables are produced by the sedatives given rather than by the trauma of labor. In an effort to answer this point, the study was repeated on those mothers who received no sedatives whatever during labor. The result of this study is shown in table 9.

It is evident from a study of these tables that the same relationship obtains as in the preceding series, which included all cases, so that the effect is apparently due to the forces of labor and not to the sedatives.

FACTORS OF DELIVERY

The influence of the type of delivery on the incidence of asphyxia was next studied. If trauma to the infant is a factor in causing asphyxia, the type of delivery should be very important. The various types of delivery were further divided into those with and those without some known type of dystocia. There were 2,660 cases in which delivery was spontaneous. The incidence of asphyxia in this group is shown in table 10. There were 1,151 deliveries by low forceps, as shown in table 11.

Chart 7.—Elective cesarean section at full term with spinal anesthesia in forty-eight cases.

Asphyxia occurs with considerably greater frequency in low forceps delivery than in spontaneous delivery. However, in most of these cases episiotomy is also performed, which necessitates anesthesia. As will be shown later, this is an important factor and probably accounts for a good deal of the increase in asphyxia in the low forceps group.

There were eighty-seven deliveries by version and extraction, in which group the incidence of asphyxia is extremely high, as shown in table 12.

There were 118 deliveries by breech extraction. The incidence of asphyxia in this group is shown in table 13.

There were 264 cases of other types of operative delivery, mostly mid forceps rotations and the like. The incidence of asphyxia in this group is shown in table 14.

Over 2 hours.....	22	4.5	13.6	81.9

A very brief inspection of this series of tables dealing with the type of delivery is sufficient to show what a tremendously important factor this is, especially when associated with dystocia. It serves to emphasize most emphatically that trauma to the infant is of major importance in producing asphyxia.

There were 108 cases of elective cesarean section and sixty-four in which labor had started. In the former the element of trauma is almost completely avoided, but the factors of anesthesia and sedation are not, as will be brought out later. In the latter group some element of trauma is added. The incidence of asphyxia in these two groups is shown in table 15.

SEDATIVE FACTORS

There were 631 mothers who received no sedative whatever during labor. Slightly more than one third of these were primiparas, so that it forms an excellent control group. The incidence of asphyxia in this group is shown in table 16.

The incidence of severe asphyxia is only 3 per cent as compared to 8.6 per cent for the series as a whole, and immediate spontaneous respiration is 88.1 per cent as compared with 75 per cent. This is a very impressive difference.

Morphine.—There were eighty-one mothers who received morphine within four hours of delivery. It has been said that morphine given during this time exerts a marked effect on the baby. There were 147 mothers who received morphine more than four hours before delivery. While the effect is not nearly as striking as in the preceding group, it is still very marked. The incidence of asphyxia in these two groups is shown in table 17.

Scopolamine.—The effect of scopolamine was studied by dividing the cases into groups based on the number of units administered; $\frac{1}{150}$ grain (0.0004 Gm.) was considered as a unit. It should be noted that in the group receiving only 1 unit the incidence of severe asphyxia is twice as great as in the group receiving no sedatives and that immediate spontaneous respiration is 10 per cent less.

Chart 3 shows in graphic form the relationship of severe asphyxia to immediate spontaneous respiration with successively increasing dosage of scopolamine. It will be seen that with each additional dose of the drug the incidence of spontaneous respiration decreases, starting at 88.1 per cent and dropping to 56.9 per cent,

and that likewise the incidence of severe asphyxia increases correspondingly from 3.3 per cent to 18.6 per cent. It should also be pointed out that the number of cases in each of these groups is of such size that all variables should be satisfactorily smoothed out, so

TABLE 14.—Incidence of Asphyxia in Mid Forceps Rotation

More than 4 hours before delivery....	147	0.0	17.7	8.8	15.6	57.8

that this actually represents a scopolamine effect. In order to answer this point more fully, however, the cases that presented any other known factor which could have contributed to asphyxia were eliminated and the study was repeated in the remaining uncomplicated cases. All cases of operative delivery or of dystocia, all cases in which the second stage of labor lasted more than one hour, all cases in which any other sedative was given in combination with scopolamine, all accidents of labor and all cases in which the mother was not well were excluded. The analysis of this group is shown in table 19. It can readily be seen that the same effect is produced by administering scopolamine when as many as possible of the other contributing factors are eliminated.

Pentobarbital Sodium.—The same procedure was followed in cases in which pentobarbital sodium was given. The unit of pentobarbital sodium was taken as 1½ grains (0.1 Gm.).

Chart 4 shows in graphic form the relationship of severe asphyxia to immediate spontaneous respiration with increasing doses of pentobarbital sodium. It seems evident that pentobarbital sodium has a direct effect in increasing the incidence of asphyxia.

Paraldehyde.—Table 21 shows the incidence of asphyxia in cases in which paraldehyde was given.

ANESTHESIA

Ether.—Cases in which ether anesthesia was given were divided into groups on the basis of the length of time during which ether was administered before the birth of the baby. The results of this study are shown in table 22.

Chart 5 presents in graphic form the relationship of severe asphyxia to immediate spontaneous respiration on a basis of the duration of ether anesthesia. A direct relationship of asphyxia to the amount of ether given is apparent.

Nitrous Oxide.—There were only 240 cases in the series in which nitrous oxide either alone or in combination with ether was given. The incidence of asphyxia in this group is shown in table 23. The small number of cases in this group does not permit of further analysis, but the somewhat higher incidence of asphyxia in this group seems very definite.

Anesthesia in Cesarean Section.—The most striking effect of general ether anesthesia on the baby is shown in cases in which cesarean section was done. There were 108 full term, elective cesarean sections done in this series. Sixty of these were done under general ether anesthesia with a high incidence of severe asphyxia and stillbirths and a very low incidence of spontaneous respiration. Forty-eight sections were done under spinal anesthesia. These two groups of cases are entirely comparable in every way. All factors of labor and delivery are eliminated, so that the striking results shown are clearly due to ether. This is shown graphically in charts 6 and 7. There are 100 babies represented on each chart. The four corners are shaded to indicate the number of babies showing varying degrees of respiratory disturbance. The black squares represent the stillborn babies, the dark gray severe asphyxia, the lighter gray mild asphyxia, the off white spontaneous, delayed respiration and the white spontaneous, immediate respiration.

SUMMARY

Five thousand consecutive deliveries at the Woman's Hospital in Detroit have been analyzed with a view of determining the relative importance of the various factors which contribute to the production of asphyxia in the newborn. The maturity of the infant, the age, parity and health of the mother, the duration of the various stages of labor, the type of delivery and the use of sedatives and anesthetics all exert important influences on the incidence of asphyxia. It should be noted that these factors frequently operate in combination.

CONCLUSIONS

1. The most important single factor in the etiology of neonatal asphyxia is prematurity.
2. The next most important factor is the trauma of labor, whether it is the normal forces of normal labor or whether it is accentuated by dystocia and operative delivery.
3. Sedatives in any amount definitely increase the incidence of asphyxia in the baby in direct proportion to the amounts given.
4. General anesthesia in any amount definitely increases the incidence of asphyxia in the baby in direct proportion to the duration of the anesthesia.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. KOTZ AND KAUFMAN AND
DRS. COLE, KIMBALL AND DANIELS

DR. C. O. McCORMICK, Indianapolis: Dr. Cole and his associates in their analyzed study of 5,000 newborn infants verify the relation of each of the several known causative factors of asphyxia and emphasize the underrated influence exerted by analgesia and anesthesia. The benefit of analgesia is no longer directed to the mother alone but to the infant as well. This view is substantiated by another recent study by Dr. Cole, which demonstrated that babies born to analgesized mothers suffer less birth shock and a less and briefer "physiologic" weight loss. However, since Schreiber has indicated the remote effects of prolonged apnea on the fetal brain, every obstetric attendant administering relief for labor pains should feel more keenly his responsibility. Analgesia and anesthesia administered without intelligent regard can be justly criticized. Dr. Cole shows the definite asphyxia-producing power of the old standby inhalation ether; likewise of nitrous oxide, and less so of the barbiturates. From all this comes the necessity of reevaluating our analgesics and anesthetics in labor. The ideal method from the infant's interest must not interfere grossly with the oxygen content of the maternal blood. In this behalf rectal ether oil is to be commended in that the mother receives the usual amount of oxygen at all times, the respiratory rate is unaffected and the respiratory tract is not obstructed by mask or mucus. From the point of view of anoxemia, the best form of an obstetric anesthesia is either ethylene or cyclopropane, preferably the latter, which allows an oxygen content of as much as 80 per cent; or, better still, local or spinal anesthesia. I should like to ask Dr. Cole how he accounts for the lower incidence of the stillbirth rate of 1.9 per cent among his 5,000 cases compared with 2.5 per cent in the city of Detroit, when 88 per cent of his series of patients were delivered under sedation or anesthesia, 55 per cent of whom were handled by the general practitioner? The relationship between duration of second stage labor and the incidence of asphyxia shown by Dr. Cole endorses prophylactic forceps and, in the minds of some, the routine internal podalic version. Dr. Kotz assists us in three ways: 1. He further demonstrates that proper analgesia does not prolong labor, increase incidence of operative delivery or affect infant mortality or morbidity. 2. He contributes additional evidence that proper analgesia lessens birth shock and diminishes initial weight loss. 3. He evaluates three popular and successful methods of analgesia and indicates their respective efficiency. The favorable showing of rectal ether is noteworthy. The incidence of low forceps was only one fourth that of either the paraldehyde or the pentobarbital sodium method, and spontaneous delivery occurred seventeen times as frequently as under either of the two.

DR. FRANKLIN F. SNYDER, Chicago: Because labor itself is by no means a simple process but is complicated often unexpectedly by unforeseen events, the addition of still another factor, namely, the use of narcotic drugs, adds one more element which must be taken into account in the calculation of how normal birth is to be attained. How can one measure the effect of drugs on the fetus, keeping separate this factor from the mechanical trauma of labor? Direct observations of the intra-uterine respiratory movements of the fetus provide an approach to this problem. In an experiment, the rate of fetal respiratory excursions of the rabbit was 30 per minute. Pentobarbital sodium was given to the mother rabbit. Fetal respiratory movements were promptly depressed and finally abolished. The mother, however, showed no such effect, being alert and having normal reflexes. If the fetus were not under direct observation, the striking depression of the respiratory system before birth would not have been detected, in view of the normal appearance of the mother. After inhibition of respiratory movements for an hour the fetus was delivered and breathed actively following birth, thus showing that there was no irreversible damage to the fetus despite the depressant effect. This experiment illustrates that intra-uterine respiration is a sensitive indicator which can detect the earliest effects of narcosis and permit evaluation of the extent to which a narcotic agent affects the fetus. The degree of narcosis may be expressed quantitatively in terms of

change in rate of fetal respiratory movements. Applying this method to compare various drugs used in obstetrics—morphine, paraldehyde, chloral, nitrous oxide, ether—the results show that most anesthetics of both nonvolatile and volatile types suppress intra-uterine respiration long before surgical anesthesia is reached in the mother. On the other hand, results with cyclopropane show that the attainment of one important objective of obstetric anesthesia is not beyond reach, namely the production of full surgical anesthesia of the mother without interruption of fetal respiration.

DR. JOSEPH B. DE LEE, Chicago: I want to talk particularly of the improvement in late infant morbidity. I want to call attention not to the toll of death but to their immediate and postponed sufferings later on in life. Imagine yourself put into a human manikin of appropriate size and driven by *vis a tergo* through the parturient canal. How would you like it? I know you would all demand cesarean section. But that is too dangerous. The milder cerebral injuries show up in the early months of life or in infant life or in late life by the finer macroscopic and even microscopic damage to the brain. Many years ago I used to do all my own postmortem examinations on babies and I noticed the great frequency of minute hemorrhages in the adrenal glands and at the base of the brain, which was sometimes sprinkled with them, and in the basal ganglions. Schreiber of Detroit has proved incontestably that asphyxia causes cerebral damage. Why may not some endocrinopathies seen by obstetricians be due to injuries which the baby suffers at birth? Regarding anesthesia causing asphyxia I think that we had better retrench a little; we have gone entirely too far in relieving the pain of childbirth. I do not mean that we should stop relieving the pain of childbirth but I should like to call a halt in the indiscriminate use of narcotics and anesthetics. I should like to recommend local anesthesia and get the patient's mind and the public mind into the proper receptivity for its widespread use. The damage to the baby's brain is produced not alone by the asphyxia but by the mild and severe traumatism of even normal labor. Let us try to reduce the traumatism of normal labor. The most important villain in increasing the traumatism of the baby's brain is solution of posterior pituitary. Mr. Chairman, I should like to recommend for next year that one whole morning, or possibly two, be devoted to these exclusive subjects: the use and abuse of anesthetics and narcotics in labor, and the use and abuse of solution of posterior pituitary in labor.

DR. L. MASON LYONS, Pierce City, Mo.: It is the duty of the members of our section to evolve unquestionably safe methods and procedures which will be available to and practical for the use of rural physicians. The great majority of babies born in this country are actually born in the country. Dr. McCormick spoke of the lesser danger of using cyclopropane and ethylene. It is impossible for me to take cyclopropane 20 miles into the country. These procedures are not practical in a rural community; neither are they safe when the obstetrician is usually alone or at best is assisted by a single nurse; when the occasion for anesthesia arises they are both too busy to bother with gas machines, rectal preparations and subsequent administration of ether and oil or paraldehyde or anything else. Since the obstetrician is not able to stay out in the country long enough to continue observation after intense narcosis, he should not even attempt their use. It is my experience that the use of barbiturates does narcotize babies. In about 200 recent deliveries I have not given a single dose of any sort of analgesia or any anesthetic. I recognize the use of anesthetics only for an obstetric emergency, and of these I recognize only operative intervention, which may be version and extraction, the necessity of performing and subsequently repairing an episiotomy or something of the sort. Forceps has not been used in my last 192 cases. It has never been taken from the bag. I decry the indiscriminate use of analgesia. If the obstetrician has the confidence of the mother, carefully explains what she must do to assist, talks to her, stands by her, her labor is easier, her pains are more tolerable, her baby is healthier, her labor is quicker and her subsequent course is more normal.

DR. M. S. LEWIS, Nashville, Tenn.: In discussing the effects of analgesia on the newborn one must recognize first that the normal fetus exists in the uterus in a constant state of cyanosis. Cyanosis, then, must be considered the normal state for the

infant at birth and becomes pathologic only if unduly prolonged. Second, it is important to distinguish between asphyxia resulting from the narcotic and that resulting from the hazards of labor. Third, one must recognize that there is extraordinary variability in the manner in which different babies will react to the same drugs. Equally true, all drugs vary widely in the relative degree with which they depress the respiratory tract. In ten years I have observed 2,000 infants born to mothers who had received various analgesics during labor. They were divided into three groups. The first group of mothers received between 12 and 15 grains (0.8 and 1 Gm.) of amytal and 4.3 per cent of the babies were narcotized. The second group received barbiturates and scopolamine, 1 or 2 units, and 15.1 per cent of the babies were narcotized. The third group received morphine and scopolamine and 18.1 per cent of the babies were narcotized. All labors were terminated under nitrous oxide and oxygen. It is hard to understand why there would be any narcosis when a mother received only 1, 2 or 3 grains (0.06, 0.13 or 0.2 Gm.) of amytal, as has been shown here today, when I use an average dose of from 12 to 15 grains and only 4.3 per cent of the babies do not breathe spontaneously. Narcosis of the newborn may be influenced by a number of factors: First, trauma of labor, the size of the dose, the interval between the administration of the analgesia and delivery, and the effects of the drug on the mother. Infants who have been subjected to a long or difficult labor are definitely more susceptible to narcosis from all analgesics administered. This is illustrated in my series: In the operative deliveries 18.3 per cent of the babies were narcotized while in the spontaneous deliveries only 7.1 per cent were narcotized. The operative group did not receive any larger dose than those in the spontaneous group. When operative procedures are anticipated the drugs administered to the mother should be used sparingly and with care, since the infants that have been traumatized may not tolerate in addition any medication that may affect the respiratory system.

DR. MEYER BODANSKY, Galveston, Texas: There can be little question that the use of paraldehyde as an obstetric analgesic carries very little hazard, at least to the adult. Dr. Kotz has submitted evidence of its relative harmlessness to the newborn. At the same time, it must be recognized that exceptional instances do arise. In fact, less than a year ago Dr. Kotz himself reported a fatal case which he and his associates described as one of "idiosyncrasy to paraldehyde" (*THE JOURNAL*, June 25, 1938, p. 2145). A similar case was reported by Drs. J. L. Jenkins and J. Herrod (*Bull. John Sealy Hosp.* 1:27 [Feb.] 1939). A primipara aged 27 received 24 cc. of paraldehyde during labor and shortly thereafter fell into a deep coma lasting forty-four hours. The patient after a subsequent stormy course managed to survive. Dr. Jenkins' case suggested the possibility that the intensity and duration of the effect of the drug were perhaps related to previously coexisting but unsuspected liver impairment. An experimental study was undertaken to determine the effect of liver damage on the pharmacologic action of paraldehyde. In this connection, methods were devised for the accurate determination of paraldehyde in body fluids and respired air. My studies thus far indicate that the presence of liver damage reduces the rate of paraldehyde destruction and greatly prolongs the blood paraldehyde curve, this being accompanied by intensification and prolongation of the narcotic effect. Although I recognize that in general paraldehyde is a relatively harmless drug, nevertheless, on the basis of experimental results, I feel that hepatic insufficiency is a contraindication to its use. Concerning the effects on the newborn, one can only speculate. It is conceivable that, though a transient rise in the concentration of paraldehyde in the blood and tissues of the fetus may be of little consequence, a high level of concentration sustained for many hours may produce a quite different effect, of the pathologic changes of which nothing is known at present. The problem is, therefore, of more than academic interest. However slight the hazard may be, it nevertheless exists, and it is important for obstetricians to keep this fact in mind.

DR. G. D. ROYSTON, St. Louis: Anesthetics and analgesics all carry some dangers in their administration. These dangers, however, are outweighed by their advantages. In the Washington University Clinic, where scopolamine has been used in more than 20,000 labors, the fetal mortality has been somewhat

lower than in labors in which no analgesia was employed, possibly because of closer supervision during this time. Before we began its use in this institution animal experimentation was conducted under the personal supervision of the professor of pharmacology, whose wife was an early patient delivered under this method. These experimental studies showed that scopolamine in doses considerably larger than those used in seminarcois had no effect on either heart or respiration. It was also found that opium in any form, whether morphine, codeine, pantopon (hydrochlorides of the alkaloids of opium, principally morphine) or narcotine (the double salt of morphine and narcotine), depressed the respiratory center and also constricted the bronchioles, hence was a respiratory depressant. It must be remembered that other factors, such as dystocia, compression of the fetal head at the vulval ring, the addition of some anoxemia from ether or gas and the like, also add to the dangers of fetal asphyxia. It is important that analgesics be given in moderate dosage. Among more than 2,000 private patients whom I delivered under scopolamine personally administered, my present technic is as follows: As soon as it is determined that the patient is definitely in active labor she is given from 1½ to 3 grains (0.1 to 0.2 Gm.) of pentobarbital sodium by mouth and scopolamine hydrobromide 1 cc. (½ grain [0.5 mg.]) by hypodermic injection; forty-five minutes later scopolamine hydrobromide 1 cc. by hypodermic and forty-five minutes later a third dose of scopolamine hydrobromide 0.5 cc. (½ grain [0.2 mg.]). Thereafter she is given 0.5 cc. by hypodermic every hour and a half to two hours until delivered. The first stage of labor is slightly shortened and the second is somewhat lengthened. The total duration of labor averaged from thirty minutes to an hour longer with analgesia. Episiotomy and the avoiding of any protracted compression of the fetal head at the introitus markedly reduced the occurrence of delayed fetal respirations and fetal and maternal trauma. The advantages of analgesia are not limited solely to the relief of pain, as their judicious employment often permits a better test of labor until a safer period for intervention (delivery) is reached.

DR. JACOB KOTZ, Washington, D. C.: Dr. Lyons made the statement that in his last 150 or 200 deliveries he used no obstetric analgesia, that he merely talked to his patients. I wonder how many of you have ever had an attack of kidney colic and had somebody talk to you and remember how much relief you got from that. We have tried to give an honest description of what really happens to babies when mothers receive obstetric analgesia. It is true that the initial respiration is slightly delayed, but these babies respond rapidly to simple methods of resuscitation. We believe that paraldehyde, the McCormick technic, pentobarbital sodium and scopolamine, used by trained obstetricians in hospitals adequately prepared for the care of the unconscious patient, are safe methods to be employed during childbirth and should result in no greater mortality or morbidity to the mother or the baby than drop ether.

DR. WYMAN C. C. COLE, Detroit: It would be impossible to answer any important part of these questions in the space at my disposal. I hope that our position has not been misunderstood. We have no thesis that we have been trying to prove and the data which we have presented are simply presented as data. In fact, if we had any objective in mind in undertaking this study it was to show that scopolamine and pentobarbital sodium were harmless. We were not able to do so. We were able to show only a small part of our study today. The other questions that have been asked of us have been answered in the rest of our study, which I will be glad to let anybody see who is interested.

Bread in Reducing Diets.—This staple article of diet is probably more responsible for over-fatness than any other single item of food. Many adults, brought up in childhood on large quantities of bread, butter and jam, suffer from a "bread habit" and find the limitation of bread which is necessary in reducing diets extremely irksome. For some it is easier to give up bread altogether than to have it rationed; they prefer to eat biscuits or rusks. As a rule, however, a little bread should be included in every diet, if only for the purpose of teaching self control.—Christie, W. F.: *Ideal Weight: A Practical Handbook for Patients*, London, William Heinemann, 1938.

THE PRODUCTION OF PERSISTENT ARTERIAL HYPERTENSION BY CELLOPHANE PERINEPHRITIS

IRVINE H. PAGE, M.D.

INDIANAPOLIS

Perinephritis apparently has not been recognized as a possible cause of arterial hypertension. Occasionally hypertension has been recorded for patients whose renal parenchyma from one cause or another has been chronically compressed. Any genetic relationship seems, however, to have been ignored.

During the course of experiments designed to prevent the development of renal cortical collateral circulation, cellophane was tried because it was believed that it would cause little damage to the tissues. It was soon apparent that arterial hypertension had developed in the animals in which cellophane had been wrapped around the kidneys. Examination showed

Fig. 1.—Effect on arterial blood pressure of applying cellophane to both kidneys.

them to be enclosed within a fibrocollagenous hull from 3 to 4 mm. thick. The cellophane had been fragmented and taken up, chiefly by the omentum.

The kidney bulged from the hull when it was cut, indicating that the parenchyma was held fast under tension.

The reaction of tissue to cellophane is extraordinary. Contact for relatively short periods (three to thirty days) is enough to evoke a proliferative reaction which continues for a time, at least, after the cellophane has been dispersed by the omentum.

METHOD OF PRODUCING PERSISTENT ARTERIAL HYPERTENSION

A dog, cat or rabbit is placed under pentobarbital sodium anesthesia, an incision parallel to the spine is made and a kidney is exposed and lifted from its bed. The fat is removed, and the organ is wrapped gently

From the Lilly Laboratory for Clinical Research, Indianapolis City Hospital.

Read before the Section on Pathology and Physiology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

A preliminary report of this work has been published (Page, I. H.: A Method for Producing Persistent Hypertension by Cellophane, *Science* 89: 273 [March 24] 1939).

in cellophane sterilized in alcohol. The material may be applied much as if one were making a bag from a flat sheet, the ends being twisted together and held in place by punch paper-clips. String may be employed if it is not important whether the hull forms around the hilus of the kidneys or not. The cellophane need not closely approximate the surface of the kidneys, and it should exert no constrictive effect. Fluid has easy egress from the bag. With dogs the kidney may be dropped back into its bed without fear that its vessels will kink, but with rabbits and cats it is desirable to place one stay suture to insure that the kidney will maintain its proper position. The wound is closed with silk. The operation should take no more than ten minutes.

Various kinds of commercial cellophane have been employed, and most of them provoke an intense fibrocollagenous reaction. Ordinary Du Pont cellophane and sylphwrap are among the best for this purpose. The moisture-proof cellophane seems less reliable. Rubber (surgical glove), tinfoil and oiled surgical silk were found useless, although plain surgical silk was satisfactory.

Blood pressure was measured by a mercury manometer connected with a tube filled with heparin solution to a needle (No. 20) inserted into a femoral artery.

RESULTS

Within three to five days a sharp tissue reaction to the cellophane occurs, and during the next two or three weeks the constricting hull forms around the parenchyma of the kidney. Hypertension occurs whether one or both kidneys are placed in cellophane after the hull has formed. Usually three to five weeks is required for severe hypertension to occur.

Fig. 2.—Kidney parenchyma surrounded by hull which does not involve the renal pedicle. The left hand arrow points to the rim of the hull, which clears the pedicle by a centimeter. The mean arterial pressure was 180 mm. of mercury. The other kidney was normal.

The hypertension may not be as marked or persistent if cellophane has been applied to only one kidney, though this is not always so. Application of cellophane to the other kidney may reinforce and stabilize the hypertension. It is usual for the blood pressure to reach a peak after the first two months, then to fall from 20 to 30 mm. of mercury and remain at an

elevated level. Dogs have maintained hypertension for a year, and there is no reason to suppose it will not continue. The arterial pressure of rabbits and cats responds in much the same way, but apparently renal insufficiency as a result of the cellophane develops in rabbits with greater ease than in other animals.

Fig. 3.—Section of kidney after fibrocollagenous hull has formed as the result of wrapping the kidney in cellophane.

Removal of the Offending Kidney.—If hypertension has resulted from applying cellophane to one kidney and then this kidney is removed, the blood pressure falls within a day or two to the control level. In two experiments the constricting hull was peeled off; in one animal the blood pressure also fell to normal, but in the other the fall was more modest. The longer the hull remains on the kidney, the more difficult it is to strip off.

Renal Denervation.—The nerve supply to the kidneys was removed by stripping the pedicle, with great care, of all visible nerves, and then cellophane was applied to the kidneys. Hypertension developed in all of four animals.

Effect of Stripping the Capsule of the Kidney.—This procedure did not prevent the hull from forming around the kidney parenchyma and the development of hypertension when cellophane was applied.

Adrenalectomy.—In some experiments, after the removal of one adrenal gland, one kidney was wrapped in cellophane. After hypertension had developed, the remaining adrenal gland was removed. The blood pressure fell to normal or slightly hypertensive levels. Removal of both glands in animals with sustained hypertension also resulted in a sharp fall in arterial pressure. If adequate doses of adrenal cortex extract and sodium chloride were administered, moderate hypertension (from 150 to 180 mm.) continued.

Occurrence of Renin Activator.—The activating power of plasma for renin was determined in six dogs made hypertensive with cellophane. The method of Kohlstaedt, Page and Helmer¹ was employed. This consists of comparing the intensity and duration of con-

1. Kohlstaedt, K. G.; Page, I. H., and Helmer, O. M.: The Activation of Renin by Blood, *Am. Heart J.*, to be published.

striction produced in an isolated dog's tail perfused with Ringer-Locke acacia solution when plasma from normal or hypertensive animals and purified renin are mixed and injected into the perfusion fluid.

It was found that the "activator," e.g. the substance in plasma which in combination with renin exerts a constrictor action on blood vessels, was definitely increased in the hypertensive dogs. The details of these experiments are contained in a communication by Kohlstaedt, Page and Helmer.¹

COMMENT

The perinephritis caused by application of cellophane to the kidneys results in the formation of a fibrocollagenous hull which constricts the renal parenchyma. It is not necessary simultaneously to constrict the renal veins, artery or ureter.

The cellophane usually is fragmented and taken up by the omentum with the result that the omentum assumes a peculiar golden brown color and is filled with nodes, each of which contains small bits of cellophane.

Fig. 4.—Effect on arterial blood pressure of applying cellophane to both kidneys and later removing both adrenal glands.

In spite of the disappearance of the cellophane from the kidneys, the hull continues to thicken for some time, though how long has not been determined.

Sufficient evidence has been collected to suggest that the physiologic mechanism responsible for the hypertension is similar to that concerned when hypertension results from constricting the renal arteries by the Goldblatt clamp. As in that type of hypertension, removal of the offending kidney abolishes the condition (Goldblatt, Lynch, Hanzal and Summerville;² Blalock and Levy³). Similarly, renal denervation does not prevent its development (Page;⁴ Collins⁵). Adrenalectomy seriously modifies the capacity of the body to respond to the hypertensive stimulus (Goldblatt;⁶ Page;⁷ Col-

lins and Wood⁸). Hypertension can be produced by applying cellophane to one kidney and is intensified and usually stabilized by applying it to both kidneys or removing one kidney and applying it to the other. The same applies to Goldblatt hypertension. And lastly, both types of hypertension are associated with an increase of renin activator in the blood (Kohlstaedt, Page and Helmer¹). Removal of the constricting hull often causes the hypertension produced by cellophane to disappear.

The technic of producing hypertension by cellophane is simple and seldom results in failure.

Studies of renal function will be the subject of a separate report in collaboration with Dr. A. C. Corcoran of the Lilly Laboratory for Clinical Research. The morbid tissue changes have been described in a preliminary communication by Dr. Irving Graef, of the New York University Medical School, and myself.⁹

SUMMARY

1. Severe persistent arterial hypertension has been produced in animals by means of perinephritis induced by cellophane and silk. As a result of the perinephritis a thick, fibrocollagenous, constricting hull is formed around the parenchyma but avoiding the pedicle. Renal ischemia is thus produced by a method different in principle from clamping the renal arteries.

2. Removal of the offending kidney or the hull around the kidney abolishes the hypertension.

3. Denervation of the renal pedicle does not prevent the development of hypertension when perinephritis is induced.

4. Bilateral adrenalectomy in untreated animals abolishes the hypertension. If treated with adequate amounts of sodium chloride and adrenal cortex extract, slight hypertension persists.

5. The amount of the substance in the blood which combines with renin to form a pressor substance ("renin-activator") is increased.

6. Perinephritis may be an additional cause of arterial hypertension in man.

ABSTRACT OF DISCUSSION

DR. ALVIN G. FOORD, Pasadena, Calif.: May I ask what are the changes in the arteries and arterioles, as well as those in the parenchyma in the kidney, after prolonged constriction of the kidney by your method?

DR. IRVING H. PAGE, Indianapolis: I should not discuss the question because I am not a pathologist. Dr. Irving Graef of the New York University College of Medicine is studying the material. For the most part, he finds relatively little change except when the malignant stage appears. There may be atrophy of the tubules and areas of fibrosis and infarction. Some of our animals have been alive for eighteen months, but such periods are too short to be certain of the ultimate morbid changes in the kidneys.

DR. FOORD: Would you expect that a similar tumor growth around a kidney in a human being would produce hypertension?

DR. PAGE: It did.

DR. FOORD: Yours was unilateral?

DR. PAGE: No, bilateral. The case was described in detail by Dr. Blatt and myself in the May issue of the *Annals of Internal Medicine*.

NONSURGICAL ASPECTS OF THE KIDNEY STONE PROBLEM

FULLER ALBRIGHT, M.D.

HIRSH W. SULKOWITCH, M.D.

AND

RICHARD CHUTE, M.D.

BOSTON

Our purpose in this paper is to report some observations which have been made at the Stone Clinic of the Massachusetts General Hospital and in the Research Laboratory since a previous brief report¹ in 1937. This paper is not meant to be a well balanced discussion of all the nonsurgical aspects of the kidney stone problem.

The approach to the entire subject has remained fundamentally the same. It is based on the following major premise and its corollary:

Premise.—A patient with urine of such composition that some crystalloid precipitates out of it is predisposed to the formation of a stone composed largely of the precipitated crystalloid (compare cystine stone in cystinuria, uric acid stone in gout and calcium phosphate or calcium oxalate stone in hyperparathyroidism).

Corollary.—In a case in which there is a tendency for stones composed predominantly of a certain crystalloid to form, treatment should be directed to altering the composition of the urine in such a way that solution of the crystalloid is favored.

It is appreciated that the problem is not quite as simple as the foregoing propositions suggest. Stasis undoubtedly is a factor. Infection, on the other hand, while definitely a factor, probably plays its chief role by changing the composition of the urine (e. g. ammonia formation producing an alkaline urine and favoring the precipitation of phosphates and carbonates).

If one is to apply the aforementioned approach, it is necessary first to know the nature of the stone with which one has to deal. If mixed stones are disregarded, there remain four common types—calcium phosphate, calcium oxalate, uric acid and cystine. Each of these stones requires its own specific measures. For example, the urine should be made acid for calcium phosphate stones and alkaline for uric acid and cystine stones. With oxalate stones the p_H of the urine is unimportant. If no stones are available for analysis, one must resort to circumstantial evidence. A few differential points seem worthy of mention.

Staghorn stones are nearly always, if not always, composed of calcium phosphate or cystine. The latter in some cases have a pathognomonic appearance in the roentgenogram (fig. 1). Very suggestive of cystine stones is the coalescence of several small stones to form a large one (fig. 1 A). The individual small stones, furthermore, have a homogeneous, waxlike appearance, which is most characteristic but hard to describe (fig. 1 B). Cystine stones, of course, occur with cystinuria, so the diagnosis can easily be ruled in or out by testing the urine for cystine.² Phosphate stones, on the other hand, grow by surface apposition and their lamellar structure is often discernible in the roentgenogram. Infection of the urinary tract by an organism which

splits urea is strong evidence that any stones which may be present are composed of phosphates and carbonates. Hyperparathyroidism usually causes calcium phosphate stones but occasionally calcium oxalate ones. A structure suggestive of a snowflake with spicules radiating from a central focus (fig. 2) is pathognomonic of calcium oxalate. Failure of the stone to show in the roentgenogram is strong evidence in favor of a uric acid stone.

DISSOLUTION OF KIDNEY STONES

It is, of course, one thing to prevent the formation of stones and another to dissolve them. A priori one might hope that, if precipitation of a crystalloid influences stone formation, the dissolving of the crystalloid from a stone might cause the disappearance of the stone. Such indeed seems to be the case. Stones, like teeth, are made of an organic matrix in which is deposited a crystalloid. However, there is one important difference. If the calcium is dissolved out of a tooth there is still a tooth; if the calcium is dissolved out of a cal-

Fig. 1.—Appearance of cystine stones in patient R. E. C. before operation: A, coalescence of small stone to form large one; B, stones with waxlike appearance

cium phosphate stone there is no stone. Such being the case, it becomes apparent that the dissolution of stones is not an impossibility.

DISSOLUTION OF CYSTINE STONES

If a cystine stone is placed in a weakly alkaline solution in the laboratory, it very gradually disappears over a period of weeks or months. Thus a cystine stone weighing 0.1292 Gm. immersed in a borate buffer solution of p_H 8.0 at 40 C. lost 14.2 mg. (11 per cent) in eleven days.

It is very simple to keep the urine alkaline, and there is no reason why a cystine stone in the kidney pelvis should not disappear. And it does. Thus a girl aged 15 whose roentgenogram is shown in figure 1 entered the clinic Feb. 1, 1938. Kidney function was only moderately impaired and, surprisingly enough, the urine was not infected. The diagnosis, at once suspected because of the roentgenogram, was confirmed by the demonstration of cystine in the urine. It was thought (we now believe ill advisedly) that surgery was indicated. When this was completed the right kidney was out; there were still some stones in the left kidney and in the perirenal tissues (fig. 3 A), and the urine was infected with *Staphylococcus albus*. The patient was

2. To 5 cc. of urine made alkaline with ammonium hydroxide 2 cc. of 5 per cent sodium cyanide solution is added and allowed to stand for from five to ten minutes; a few drops of a freshly prepared 5 per cent sodium nitroprusside solution is then added; in the presence of cystine a permanent deep purplish red will develop.

then put on sodium citrate, 1 teaspoonful three times a day, to keep the urine alkaline. The intrarenal stones gradually disappeared (figs. 3 A and B). The urinary infection has persisted.^{2a} The end result will probably be fairly satisfactory. Another time, however, we would try medical treatment from the beginning. These observations with regard to cystine stones, of course, have been made³ before the present reports.

Fig. 2.—Appearance of calcium oxalate stones from two different patients. B is that of patient referred to in the text.

DISSOLUTION OF CALCIUM PHOSPHATE STONES

The problem with calcium phosphate stones is not so simple. Expose a calcium phosphate stone to an acetic acid solution at a p_H of 5.0 in the laboratory and in a very few days there is no stone. Keep the urine of a patient with a calcium phosphate stone in the kidney pelvis at a p_H of 5.0 for several months; the stone will become no larger but in most cases it will become no smaller. There is no question that the Higgins regimen,⁴ one of the main features of which is the production of an acid urine, will cause an occasional calcium phosphate stone to disappear; the question is why the regimen does not work better than it does. The answer is quite apparent. The urine is very nearly saturated with calcium phosphate when it reaches the stone. The more acid the urine the more calcium and phosphate ions it will keep in solution, but the more acid the urine the more calcium and phosphate ions it already contains when excreted by the kidney. If one could cause the patient to excrete an acid urine without

The logical sequel to this discussion is a consideration of the advisability of introducing some dissolving fluid into the kidney "from below" by a catheter. A study of what might be the most efficacious fluid to use has been under way in this laboratory for the past eight months. We are far from having all the answers, but a few simple facts seem clear.

The solution should probably be as acid as possible without being too irritating to the tissues. Urine can reach a p_H of 4.8. Solutions with a p_H of 4.0 seem to cause but little irritation, and this figure has arbitrarily been chosen for the time being.

The next question is what acid to use. Strangely enough, urologists in the past frequently have attempted to dissolve phosphatic calculi with phosphoric acid. This is the one acid not to use (v. infra). Citric acid has a property other than the fact that it is an acid, which suggests its use for this purpose. Dr. M. J. Shear several years ago first called the attention of one of us (F. A.) to the possibility of using citric acid for this purpose. It took a few simple test tube experiments performed in July 1938, however, to show us how efficacious citrate really is.

Fig. 4.—Rate of solubility of kidney stones in vitro at different p_H 's with sodium citrate, citric acid mixture of 154 mm. per liter (isotonic): A, calculus consisting mainly of calcium oxalate, citrate solution p_H 4.0, temperature 25 C. B, fragment of calculus consisting mainly of calcium phosphate, citrate solution p_H 8.0, temperature 30 C. C, fragment of calculus from same stone as (B) at p_H 5.0, temperature 30 C. D, calculus consisting mainly of calcium phosphate, citrate solution p_H 5.0, temperature 30 C.

Before discussing the test tube experiments, it may be helpful to explain the specific property of citric acid previously mentioned. The following equation will help make this clear:

It will be noted from the equation that the net result of adding citrate ions to a solution containing Ca ions is to divide the number of Ca ions by 3. The other two thirds of the Ca ions become caught in a complex $(\text{CaCit})^-$ ion. Unfortunately this property of citrate solutions is at its maximum only at alkaline p_H 's; at more acid p_H 's there is little of the tertiary citrate $(\text{Ca}_3\text{Cit}_2)$ formed and more of the secondary (CaHCit) and primary $(\text{Ca}[\text{H}_2\text{Cit}]_2)$ citrates, neither of which produce $(\text{CaCit})^-$ ions. However, both of these salts are weakly dissociated, so there is a marked reduction of calcium ions even at a p_H of 4.0. One can calculate the calcium ion concentration, given the total calcium, the citrate concentration and the p_H , from a nomogram constructed by McLean.⁵

5. McLean, F. C.: Application of the Law of Chemical Equilibrium (Law of Mass Action) to Biological Problems, *Physiol. Rev.* 18:495 (Oct.) 1938.

Fig. 3.—Appearance of cystine stones of patient R. E. C. (see figure 1). A, April 16, 1938, shortly after right nephrectomy and left nephrolithotomy; B, after ten months on medical regimen. Note that most of stones in the kidney have disappeared.

at the same time increasing the calcium and phosphate in the urine, the in vivo results should approach the in vitro ones.

2a. Urinary infection subsequently cleared up spontaneously.
3. Crowell, A. J.: Cystin Nephrolithiasis, *Surg., Gynec. & Obst.* 38: 87 (Jan.) 1924.
4. Higgins, C. C.: Urinary Lithiasis: Experimental Production and Solution with Clinical Application and End Results, *J. Urol.* 36:168 (Aug.) 1936.

The importance of this property of citrate is obvious. The speed of solution of calcium phosphate salts in any fluid will be decreased as the calcium or phosphate ions increase; any property of a fluid which will dispose of one of the end products of the reaction—in this case calcium—will speed up the reaction. The objection to phosphoric acid (v. supra) is, of course, that it supplies

Fig. 5.—Rate of solubility of phosphate kidney stone in sodium citrate-citric acid mixture of 154 mm. per liter (isotonic) at pH 4.0, temperature 25 C. Where loss in weight is not due to citrate solution points are not connected with a line.

The most significant of these experiments is 3, in which a calcium phosphate precipitate is dissolved in an alkaline urine by adding sodium citrate. Experiment 5 suggests that a citrate solution will not help to redissolve oxalates, at least of an acid p_H , although it hinders precipitation of oxalates (experiment 6). More elaborate quantitative studies were designed to determine the effect of temperature, concentration, p_H , other salts and the like, but these are not yet completely satisfactory and will not be discussed here, especially since it appears possible that citrates may be superseded by hexametaphosphate (discussed later). The citrate solution which we used for the in vivo experi-

TABLE 1.—Six Experiments

1. Urine + ammonium hydroxide → calcium phosphate precipitate
2. Urine + ammonium hydroxide → calcium phosphate precipitate + acetic acid → clear solution
3. Urine + ammonium hydroxide → calcium phosphate precipitate + sodium citrate → clear solution
4. Urine + oxalate → calcium oxalate precipitate + acetic acid → no change
5. Urine + oxalate → calcium oxalate precipitate + sodium citrate → no change
6. Urine + sodium citrate (stand 1 hr.) + oxalate → inhibited precipitate

ment discussed later had a p_H of 4.0 and a concentration of citrate which was twice isotonic. Its formula is given in table 2. This is not altogether nonirritating.

EFFECT OF CITRATE SOLUTION ON CALCIUM PHOSPHATE STONES IN VITRO

Quite a large number of experiments have been conducted in which phosphate stones have been subjected to a constant interchange of the citrate solution at various temperatures, and their reduction in size has been noted. Some representative experiments are shown in figures 4, 5 and 6. The speed with which the stones dissolved was most encouraging. Some stones crumble; others decrease in size without crumbling.

IN VIVO EXPERIMENTS ON CALCIUM PHOSPHATE STONES

To date the solution has been tried on four patients. There has been only one convincing success. This patient (C. S.) was a hemophilic youth aged 19 who had had a hemorrhage into the spinal cord. This had resulted in a partial paralysis of the lower extremities and a "cord bladder." He had been bedridden for three years and had been on constant drainage for two years. In the lower extremities osteoporosis had occurred from disuse. The urine was constantly alkaline, owing to

TABLE 2.—Citrate Solution Used

Sodium citrate	45.2 Gm.
Citric acid	38.0 Gm.
Distilled water.....to make	1,000.0 cc.

infection, and the bladder contained nine large laminated stones (fig. 7). One of us (R. C.) saw him in consultation and thought that any surgical procedure was contraindicated. Accordingly the citrate solution was administered to the bladder by Munro's⁶ tidal drainage apparatus. The stones rapidly disappeared, as shown in figures 8 and 9. It may be asked how it is known that the stones were destroyed rather than just decalcified. Figure 8 answers this. If the matrix remained intact, the calcified remnants would not be touching one another.

In the three other cases there was no cause for discouragement, as definite reasons for the lack of success were present and as these can be avoided in the future. One of these cases will be discussed later.

APPARATUS FOR DISSOLVING STONES IN KIDNEY PELVIS

Needless to say, the object of these studies is based on the hope that a stone in the kidney pelvis can ultimately be dissolved by means of a ureteral catheter. An apparatus has been designed for alternately introducing fluid into and withdrawing it from the kidney pelvis. The principle behind this apparatus is the same as that in Munro's tidal drainage apparatus for the bladder. Some of the most important features of this apparatus and the initial impetus were furnished by Dr. William Davis. If the apparatus proves practicable, a description will be published under the authorship of two of us (F. A. and H. W. S.) and Dr. Davis. In its present form it was tried recently on a patient with a large stone in the kidney pelvis which

Fig. 6.—Rate of solubility of kidney stones in sodium citrate-citric acid mixture of 154 mm. per liter (isotonic) at pH 4.0, temperature 40 C. A and C, calculi consisting of a large amount of calcium phosphate and some calcium carbonate. B, calculus consisting of a large amount of calcium phosphate and a moderate amount of calcium oxalate.

had resulted from hyperparathyroidism. The apparatus was run for three days. The kidney filled and emptied satisfactorily, as determined by introducing 7.5 per cent sodium iodide into the apparatus and roentgenographing the patient. The stone showed no change. It was then

Fig. 7.—Stones in bladder before treatment.

removed and found to be an oxalate stone, which of course explains the failure.

The encouraging feature about this case was that the urine was sterile at the beginning and at the end of the three day run. She received sulfanilamide throughout. After the operation, however, the urine became infected.

SODIUM HEXAMETAPHOSPHATE

Prof. A. Baird Hastings suggested to us the use of sodium hexametaphosphate. The principle is the same as with citrate except that, whereas citrate disposes of only part of the calcium ions, hexametaphosphate disposes of all by merging them into complex calcium metaphosphate ions.

Fig. 8.—Appearance of stones shown in figure 7 after eighty hours of treatment.

The equations are as follows:

Sodium hexametaphosphate, as was to be expected, has been found most effective in the dissolving of stones in vitro. Best of all, it will actually dissolve calcium oxalate in a test tube. Of course it is not a biologic substance and metaphosphates (PO_3) do not appear in the body, so considerable caution must be exercised in its use. Recent studies in this laboratory by Dr. Max

Rosenheim and Dr. Howard Suby have shown that sodium hexametaphosphate has a marked tendency to produce hemorrhages when introduced into the bladders of dogs.

SUMMARY

The following points are selected as the most important:

1. Cystine stones can often be diagnosed by their roentgenographic appearance.
2. A stone which gives the appearance by roentgenogram of a snowflake with spicules radiating from a central focus is composed largely of calcium oxalate.
3. Attempts to dissolve calcium phosphate stones by making the urine acid are attended with little success because acid regimens increase the amounts of calcium and phosphate in the urine and thus tend to render it saturated. The question of introducing a dissolving fluid "from below," therefore, is brought up.
4. A solution of sodium citrate-citric acid at a p_H of 4.0 is effective in dissolving calcium phosphate stones in vitro and in vivo (one case of stones in the bladder). This solution combines the effect of acids

Fig. 9.—Appearance of bladder shown in figures 7 and 8 after ten more days of treatment. After still five more days of treatment stones had entirely disappeared, except for one small shadow, which persisted in spite of further treatment.

in dissolving phosphates with a specific effect of citrate in dissolving calcium salts by decreasing the calcium ion concentration.

5. More recent and less complete studies suggest that sodium hexametaphosphate solutions may be even more effective than citrate ones.

ABSTRACT OF DISCUSSION

DR. CHARLES C. HIGGINS, Cleveland: Dr. Albright and his associates are to be congratulated on the excellent results they have secured in the dissolution of bladder stones. In considering the advisability of utilizing the high vitamin A acid-ash diet to produce the dissolution of a calculus which forms in urine the reaction of which is alkaline, the authors have mentioned a fact which I have been aware of for a long time. That is, by increasing the acidity of the urine one definitely increases the excretion of calcium; however, to offset this, I have observed that the solubility of the stone-forming salts increases more rapidly with increasing acidity than does the amount of calcium excreted. It is necessary to call attention to the fact that chemical formulas indicate only the ultimate products that may be obtained and in no way suggest the time required for equilibrium to be reached. Thus, while it is pos-

sible to say that by the formation of a complex citrate ion two thirds of the calcium ions may be removed from solution, there is no way of knowing that in the concentration of calcium involved and in the presence of the other constituents in the urine this equilibrium will be reached within a reasonable length of time. This will be especially true in cases of phosphates. When one recalls the work of Holt, LaMer and Chown, in which they found that equilibrium between calcium hydroxide and phosphoric acid was reached only after ten days had elapsed, the seriousness of this problem becomes more apparent. I have in my possession roentgenograms revealing stones composed of salts which had precipitated in urine the reaction of which was alkaline or acid, in which the high vitamin A acid-ash or alkaline-ash diets have been used. These roentgenograms have been sent to me by Dr. William Braasch, of the Mayo Clinic; Dr. W. M. Kearns, of Milwaukee, and Professor Pyrah, of Edinburgh, Scotland; the last case was a staghorn cystine stone which has undergone solution by the alkaline-ash diet in my own hands. I now have a series of fifty-two collected cases in which renal calculi have undergone solution by dietary means. The results of this study will be published in the near future.

Clinical Notes, Suggestions and New Instruments

PERFORATION OF THE JEJUNUM DURING A GASTROSCOPIC EXAMINATION OF A RESECTED STOMACH

JOHN M. RUMBALL, M.D., ROCHESTER, N. Y.

To the best of my knowledge there is no report in the literature of a perforation of the stomach or of the jejunum induced by the Wolf-Schindler gastroscope with a rubber finger tip. Five perforations of the stomach have occurred with the round rubber or sponge tip of Henning on the Wolf-Schindler gastroscope.¹ Three of these perforations were observed by Dr. Rudolf Schindler of the University of Chicago Clinics. The Henning tip has been discarded by most men doing gastroscopies since the report of these accidents.

The subject of the present report had been examined gastroscopically six months before, and at this time the Henning tip had been used. The gastroscope was introduced without any force into the jejunum and was then withdrawn so that the stoma could be observed. The patient had had a resection for carcinoma, and since it is my policy to examine these cases gastroscopically at least every six months or oftener if necessary, the examination described here was just a routine follow-up.

REPORT OF CASE

Mrs. F. K., aged 68, white, was admitted to the Rochester General Hospital Sept. 13, 1938, complaining of "stomach trouble" for the preceding three months. The predominating symptoms were weakness, constipation and excessive "gas." There was a mild secondary anemia and the gastric analysis showed a low acidity. The free hydrochloric acid reached only 18 degrees thirty minutes after the administration of histamine. The radiographic study of the stomach revealed a filling defect involving the antral portion of the stomach on the greater curvature side and extending back toward the body.

September 26 a gastric resection of the modified Polya type was done by Dr. D. C. Houghton, senior surgeon in the ward service. The loop of the jejunum was brought up posterior to the mesocolon. The resected portion showed a large crater-like ulcerating tumor, which was classified as a medullary carcinoma by our pathologist. There were no metastases noted anywhere in the abdomen. Two omental nodes were removed, but these showed no evidence of carcinoma. The operation was followed by a transfusion, and the patient made an uneventful recovery. She was discharged on her twenty-sixth postoperative day. Since her discharge she has gained 15 pounds (6.8 Kg.) and her only complaint is occasional "heartburn."

The first gastroscopic examination in January 1939 revealed an adequate stoma, which, however, did not contract rhythmically. There was some increase in the normal red appearance about the stoma. The mucosa of the remaining portion of the stomach showed some atrophic changes. No evidence of recurrence of the malignant condition was seen.

The second gastroscopy was done on the morning of June 15, 1939, at 10:30. The patient was prepared in the usual manner, and the Wolf-Schindler gastroscope with a rubber finger tip was introduced with ease, no force being used. After introduction no pain or discomfort was experienced by the patient. As is often the case, the gastroscope was believed to have slipped into the jejunum. The instrument was withdrawn about 4 or 5 inches and air was introduced. The stoma and the remaining portion of the stomach appeared much the same as on the previous examination. No evidence of a malignant growth was seen. The whole examination was carried out without any difficulty. Immediately after the examination the patient complained of a feeling of distention and faintness. No shoulder pain was noted by the patient. She remained in bed in the outpatient department for about an hour and as she said she felt better she was allowed to go home. Close to 5 o'clock the same day she returned to the emergency department complaining of the same distention and generalized pain in the abdomen. A roentgenogram of the abdomen taken with the patient on her left side showed a large amount of air under the right diaphragm.

Laparotomy was performed by Dr. Christopher D'Amanda, senior surgeon in the ward surgical service, approximately nine hours after perforation. Free air escaped as soon as the peritoneum was opened, and the abdomen flattened out. Exploration through the mesocolon in the lesser sac revealed a perforation about the size of a dime (18 mm.) on the posterior surface of the jejunum 2 inches away from the stoma, as shown in the accompanying illustration. The perforation was closed and the edges were invaginated. No evidence of peritonitis could be seen, nor were there any metastatic lesions notable. The patient recovered from this insult remarkably well and was asking for a full course meal on her second postoperative day. There was a low grade fever for five days, but the temperature returned to normal and she was discharged on her fifteenth postoperative day feeling fine.

COMMENT

The incidence of this type of perforation is very small and should in no way influence one's faith in the gastroscope as a diagnostic aid; however, it has changed my method of introduction in patients who have had a resection. I believe that one had better be on the safe side and stop the introduction of the instrument at a point where the examiner believes he will best see the stoma. The one important and interesting factor in this case is that all gastroscopic signs of perforation were lacking. Usually the stomach collapses and one is unable to see very much because no air can be introduced. The stomach retained air sufficiently for me to see practically the entire mucosa in this case.

This perforation occurred in the 112th gastroscopy that I have done since October 1938. I feel that the technic that has been followed is in accord with the teachings of Dr. Schindler. The only other question that can be raised is whether the tissue at the point of perforation was normal. No biopsy was taken; it appeared normal to the surgeon, however. With these possibilities eliminated, the only conclusion that one can draw is that this perforation occurred with reasonably good technic and through normal tissue.

COCCIDIOIDAL PERITONITIS: DIAGNOSIS BY
PERITONEOSCOPYJOHN C. RUDDOCK, M.D., AND ROBERT B. HOPE, M.D.
LOS ANGELES

This case is unique in that it is the first case of coccidioidal peritonitis reported in the literature in which a diagnosis was proved before death. Coccidioidal granuloma is a rare disease and one peculiar to the San Joaquin Valley in California. The first human infection was reported by Wernicke¹ in 1892, and the organism was described as a protozoa. In 1900 Ophuls and Moffitt² proved that the infection known as coccidioidal granuloma was due to a mold (*Coccidioides immitis*) and were able to grow it on culture mediums. Many reports have appeared since this date.

The similarity of this disease to tuberculosis is noted repeatedly in the literature. This similarity exists in its clinical manifestations and body reactions to the infection. Coccidioidal infections often are miliary and it is impossible without a biopsy or culture of the organism to differentiate them clinically or by roentgenogram from tuberculosis. The x-ray appearance of bone lesions is identical with the appearance of lesions caused by the tubercle bacillus.

Although coccidioidal infections have identical clinical manifestations with tuberculosis, nevertheless intestinal and peri-

Section of tissue.

toneal infections seldom occur and are rarely seen. Greaves³ has reported the only case of intestinal infection, which he demonstrated post mortem in a Negro dying of miliary coccidioidal granuloma. Ophuls⁴ in 1929 stated that "intestinal lesions have never been discovered in coccidioidal granuloma."

The following case report demonstrates the value of peritoneoscopy in determining intraperitoneal disease, and the value of obtaining a biopsy.

History.—Y. S., a man aged 35, Japanese, single, entered the hospital Dec. 23, 1937, complaining of swelling of the abdomen and pain in the abdomen of two weeks' duration. Two weeks before entry he began to have pain in the epigastrium. With the onset of pain his abdomen had begun to swell and was progressing in size. Loss of weight was slight. He did not have fever or chills. He did not vomit but had occasional nausea; no hematemesis or melena was present. There had been no symptoms of cardiac or respiratory disease. No jaundice was observed.

The patient was born in the Hawaiian Islands; he had lived in and about Los Angeles for the past eleven years. The

patient stated that he had not resided in the San Joaquin Valley. He had a lesion of the penis in 1936 for which he received no treatment. For the past four years he had been a heavy user of alcohol, drinking both beer and whisky.

No history of familial diseases was given.

Examination.—The temperature was 99.6 F., pulse 96, respiration 20 and blood pressure 140 systolic, 100 diastolic. The patient was poorly nourished, showing recent loss of weight. There were no petechiae or cutaneous eruptions. The teeth were carious. The tongue was coated. There were palpable epitrochlear and cervical lymph glands. The chest was resonant throughout, expansion was equal and the bases moved normally. There were no rales, but hoarse breath sounds were heard at the right base. The heart showed no enlargement, regular rhythm and no murmurs. The abdomen was distended and tense with a definite fluid wave; no masses or organs were palpable. There was pitting edema of the ankles, grade 2.

The Wassermann reaction was negative. Blood examination revealed hemoglobin 75 per cent, red blood cells 3,830,000, white blood cells 13,500, neutrophils 85 per cent, mononuclears 6 per cent, lymphocytes 9 per cent, no pathologic cells. Sedimentation time was 63 mm. in one hour uncorrected, 25 mm. in one hour corrected. Packed cell volume was 28. The urine was normal.

The clinical diagnosis was atrophic cirrhosis (Laënnec).

December 24, paracentesis was done and 4,000 cc. of straw colored fluid was removed. The patient continued to have a low grade fever and to develop more ascites.

December 30, peritoneoscopy revealed dense adhesions of the omentum to the epigastric peritoneal surfaces. All peritoneal surfaces were covered with miliary tubercles. The liver and gallbladder were normal. A section of peritoneum containing tubercles was removed for biopsy. The abdominal cavity was filled with oxygen.

The impression was probable tuberculous peritonitis, but final diagnosis awaited the result of biopsy.

The pathologic examination of the tissue revealed tubercle-like nodules containing *Coccidioides immitis*. Culture of the peritoneal fluid yielded *Coccidioides immitis*. Immediately following peritoneoscopy an x-ray examination of the chest was reported negative.

Course.—Ascites returned and the patient had to have paracentesis performed from time to time. He had a septic temperature of from 100 to 102 F. and failed steadily. Jan. 21, 1938, he suddenly began to have dyspnea and for the first time discomfort in the chest. Examination revealed the typical signs of a bilateral pleural effusion. The fluid was aspirated and *Coccidioides immitis* was demonstrated by culture.

The patient died January 25.

Autopsy.—January 27, the left pleural space was found to contain 1,000 cc. of straw colored fluid, the right, 1,100 cc. The parietal pleura was studded with granulomatous tubercles. The lungs externally were studded with a granulomatous, fibrinous exudate. Tiny tubercles were seen in the parenchyma. The tracheobronchial lymph nodes were only slightly enlarged.

When the peritoneum was opened the entire cavity and intestines were seen to be covered with a thick layer of plastic exudate, which was diffusely infiltrated with nodular granulomatous tubercles, averaging from 0.5 to 1 cm. thick and extending from over the diaphragm to the pelvis. The greater omentum was from 1 to 2 cm. thick and densely infiltrated. The wall of the lesser curvature of the stomach was infiltrated from the external surface inward by granulomatous tissue. The lymph glands in this area were greatly enlarged and caseous, averaging 2 to 4 cm. in diameter. The duodenum, the small intestine and the large intestine were covered with the same thick granulomatous tissue. The mesentery was infiltrated and the glands were enormously enlarged, up to 4 cm. in diameter. Wet smears showed many *Coccidioides immitis* organisms.

The liver and spleen showed some infiltration with granulomatous tissue and tubercles.

The left kidney showed a small collection of tubercles on cross section. The bladder showed infiltration with granulomatous tissue.

The anatomic diagnosis was (1) coccidioidal granuloma; (2) coccidioidal lymphadenitis, generalized; (3) coccidioidal perito-

From the Department of Peritoneoscopy, Los Angeles County General Hospital.

2. Ophuls, William, and Moffitt, H. C.: A New Pathogenic Mold, *Philadelphia M. J.* 5: 1471, 1900.

3. Greaves, F. C.: Coccidioidal Granuloma with Lesion in Small Intestine, *U. S. Nav. M. Bull.* 32: 201 (April) 1934.

4. Ophuls, William, in discussion on Coccidioidal Granuloma, *J. A. M. A.* 93: 1055 (Oct. 5) 1929.

nitis, generalized; (4) coccidioidal pleuritis, bilateral with effusion; (5) coccidioides of spleen; (6) coccidioides, miliary, of liver; (7) coccidioides of left kidney.

The clinical course with the development of ascites and a history of alcoholism supported a diagnosis of cirrhosis. The conditions as noted with the peritoneoscope were similar to those of tuberculosis of the peritoneal cavity, and oxyperitoneum was instituted as a treatment procedure. Differential diagnosis between tuberculosis and coccidioidal granuloma is not possible without biopsy or culture. A biopsy of the parietal peritoneum and a culture of the fluid revealed *Coccidioides immitis*, thus establishing the diagnosis.

The technic of the procedure of peritoneoscopy is described in detail in previous papers by us.⁵

INHALATION OF MASSIVE AMOUNTS OF VEGETAL FOREIGN BODIES

W. A. McNICHOLS, M.D., DIXON, ILL.

On July 4, 1939, a girl aged 7 years jumped from a load of hay into a bin of finely ground dry feed containing oats, wheat, corn and corncobs. She sank into this mixture as though it were a liquid, being completely submerged with the exception of one hand. Her brother saw her jump and then he heard two frightened cries. He summoned their father, who with great difficulty was able to extricate her. It is believed that she was submerged for at least ten minutes.

When she was removed from the bin she was cyanotic, unconscious and not breathing. Her mother, who had had nurses' training, cleaned out her daughter's nose and mouth and gave her artificial respiration. Breathing was restored, but it was very rapid and shallow and the cyanotic condition did not improve.

Drs. D. L. Murphy and R. L. Baird, of Dixon, five miles distant, were summoned. They could not obtain breath sounds anywhere over the patient's chest. They wisely elected to move her to the Dixon Public Hospital, where they would have oxygen and bronchoscopic assistance.

The patient arrived at the hospital approximately thirty-five minutes after she jumped into the bin. She was unconscious and cyanotic and had rapid stridulous breathing; the pulse was thready and not countable; no breath sounds were audible anywhere over the chest, and the rate of diaphragmatic movement was from 70 to 80 per minute.

Oxygen was immediately administered by mouth through a catheter. Drs. Murphy and Baird felt that any new insult to the lung would be fatal, so they asked me to do a dry tracheotomy rather than risk losing foreign bodies at the glottis. This we did without anesthesia, all bleeding being stopped before the trachea was opened. The tracheotomy did not improve the patient's condition.

A 5 mm. bronchoscope was inserted through the tracheotomy wound. The trachea was filled with a mushy viscid fluid. After aspiration of the fluid, the bronchoscope was filled with many vegetal foreign bodies. The condition of the trachea proved my colleagues' good judgment in not using a life saver tube or attempting an emergency tracheotomy, as either procedure would have been futile and probably disastrous.

In one hour and twenty minutes, 3¾ drachms (15 Gm.) by volume of oats, wheat, corn and corncobs was removed from the tracheobronchial tree. Five pieces of corncob that were too large to go through the 5 mm. bronchoscope were removed. It was necessary to remove the instrument many times to clean it of the mushy debris. As the bronchi were cleaned out, breath sounds would appear over the corresponding areas. All this time oxygen was being given into the trachea.

Finally no more foreign bodies could be found. The trachea was stitched open with silkworm sutures anchored to the skin. No tube was used. Thus the patient was able to cough out the viscid mucus and foreign bodies.

She was placed in bed with the foot of the bed elevated and oxygen blowing into her trachea. The cyanosis had completely disappeared and breath sounds could be heard over the entire chest. The temperature was 102.8 F., the pulse rate 134, the respiratory rate 40 and the white blood cell count 21,300. Two hours later the child was conscious and able to take liquid nourishment.

The tracheobronchial tree was aspirated as needed, which was at least hourly. From the tracheotomy wound one whole oat kernel was recovered, and the suction apparatus brought out many finer pieces of grain.

The second evening the patient had a chill, with the temperature 103 F., pulse rate 156 and respiratory rate 60. The mucus was blood stained, and pneumococcus type III was found in it. She was given 5 minims (0.3 cc.) of digitalis every four hours for three doses, and 7½ grains (0.5 Gm.) of sulfapyridine, one-eighth grain (0.008 Gm.) of phenobarbital and 5 grains (0.3 Gm.) of sodium bicarbonate every four hours. She immediately improved, but after the tenth dose she began vomiting the medicine and refusing food, so all medication was stopped. By this time her temperature was 100 F., pulse rate 96 and respiratory rate 36. Her appetite returned as soon as the sulfapyridine was discontinued.

On the sixth day, with the temperature 100 F., pulse rate 84 and respiratory rate 32, x-ray examination of the lungs showed them to be clear. A bronchoscope was again inserted and a careful search was made of the tracheobronchial tree for vegetal foreign bodies, but none were found.

On the seventh day, with the temperature 98.6 F., pulse rate 76 and respiratory rate 20, the stitches were removed from the trachea and it was allowed to close. The patient was discharged on the ninth day. She has been seen from time to time, and she is perfectly well.

CONCLUSIONS

1. Inadvisable use of life saver tubes or emergency tracheotomies may frequently be of more harm than good.
2. Oxygen is a great adjunct in treatment in all cases of air deficiency.
3. Sulfapyridine may control nicely an otherwise fatal tracheobronchitis.

SEVERE ALLERGIC DERMATITIS FOLLOWING THE PARENTERAL USE OF THEELIN

LOUIS A. LEVISON, M.D., TOLEDO, OHIO, AND JULIAN J. HARRISON, M.D., NAPOLEON, OHIO

The following case seems worthy of being reported because of its rarity and the severity of the reaction.

Mrs. W. G. M., aged 51, a housewife, white, had been under the observation of one of us (J. J. H.) for several months before admission to St. Vincent's Hospital Dec. 29, 1938. She had been experiencing emotional disturbances incidental to the menopause, and a course of treatment with theelin had been proposed and put into effect. She entered the hospital on account of a marked painful, red, erythematous, swollen involvement of the skin over the anterior surface of each thigh. She stated that she had never had any similar skin trouble, and there was no history of allergic dermatitis, hay fever, asthma or food intolerance. The history revealed diphtheria at 4, a pelvic operation at 32 and a left-sided renal calculus removed at operation at the Mayo Clinic at 35. She had three children, who were living and well. A careful inquiry revealed no allergic antecedents.

The cutaneous lesions had first appeared four weeks prior to the hospital admission and during the course of a series of parenterally administered theelin beginning about Nov. 10, 1938. She had been given eight injections of theelin (Parke, Davis & Co.), each 2,000 units, over the anterior aspect of the left thigh, and one injection of estrone (Eli Lilly & Co.) 2,000 units in the same relative area of the opposite side. The injections were rather painful and itched from the outset, with the redness and rash noticeably apparent at the fourth or fifth treatment. This troublesome and distressing reaction progressively

5. Ruddock, John C.: Peritoneoscopy. *West. J. Surg.* 42: 392 (July) 1934; *Surg., Gynec. & Obst.* 65: 623 (Nov.) 1937. Hope, Robert B.: Differential Diagnosis of Ectopic Gestation by Peritoneoscopy, *ibid.* 64: 229 (Feb.) 1937.

increased in severity and area during the remainder of the course of treatments.

Examinations before and after the hospital admission did not reveal relevant manifestations other than the cutaneous condition. Her complaints were subjective, indicating the emotional and nervous instability mentioned. The skin over the anterior surface of each thigh was red and swollen, itched and was markedly erythematous. Superimposed on this angry appearing erythema were many small papules and occasional small vesicles. The greatest intensity of the inflammation on each thigh centered at the point of hypodermic injections midway between the hip and the knee. Practically the entire anterior

Extensive involvement of both legs after parenteral use of theelin.

aspect of each thigh was involved on the date of her hospital admission. The erythema spread rapidly while she was in the hospital, quickly progressing at each area of involvement to an appearance characteristic of allergic dermatitis. It reached such distant points as the ankles and neck by the fourth day. The skin was not uniformly involved but the reaction was most severe over the thighs, both ankles and the lateral aspects of the neck on each side. There was, however, general erythema of all body areas. Both ankles showed considerable swelling with a 2 plus pitting edema. There was no involvement of the mucous membrane. The itching was extreme and at times almost intolerable, doubtless accentuated by the nervous and emotional instability. Fever was not present, the urine remained normal, and the eosinophil count of the blood never exceeded 3 per cent.

Treatment consisted of palliative measures with most relief from a constantly applied lotion containing calamine, menthol, camphor, zinc oxide and solution of calcium hydroxide. Starch baths in a full tub were given several times a day. Hot or cold compresses of saturated solution of aluminum acetate were not apparently helpful. Olive oil relieved the subsequent dryness of the skin.

The patient returned to her home on the eleventh day after admission to the hospital with the cutaneous lesions greatly improved. The generalized pruritus persisted and was very troublesome. The lotion and starch baths gave relief until its subsidence several weeks later.

Inquiry of Eli Lilly & Co. revealed that the fatty solvent used in the marketed ampule was highly purified cottonseed oil, and in the product of Parke, Davis & Co. (theelin) it was peanut oil. The patient had received eight injections of the peanut oil product prior to the single injection of the cottonseed oil preparation. Each company supplied samples of the respective oils used. Patch and scratch tests of each oil were later made on the patient and gave negative results. Later, intradermal tests were made on the flexor surface of each forearm, peanut oil being used on the one side and cottonseed oil on the other. The reaction to each was unmistakable, immediate, severe and widespread. There was a large area of swelling, redness and erythema on each side, spreading over the entire flexor surface of the arm. There was no appreciable difference in the degree or extent of area involved on either side. A few

days later scattered areas of involvement appeared over the skin generally, especially on the legs, trunk and neck. The lesions were entirely comparable with the original trouble. A severe and generalized pruritus followed in the same manner as before, responding to the same management.

We have not found in the material available to us references to dermatitis of allergic origin following the parenteral administration of theelin (estrone) in oil. Inquiry among physicians in this community with wide and extensive experience has not supplied a similar instance. It is probably infrequent, although allergic responses of one type or another are not rare or unusual following the use of cottonseed oil by ingestion in the preparation of food. It does not appear that the estrogenic substance itself was a factor in this reaction. Earlier recognition of similar cases will permit substitution of other methods of administration, such as water soluble preparations, tablets or suppositories.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT ON VITAMIN K: II

SINCE THE PUBLICATION OF A PRELIMINARY REPORT ON VITAMIN K BY ALBERT M. SNELL IN THE JOURNAL FOR APRIL 15, 1939, THERE HAS BEEN WITNESSED INTENSE INTEREST IN ATTEMPTS TO ISOLATE COMPOUNDS HAVING VITAMIN K ACTIVITY. VERY DEFINITE PROGRESS HAS BEEN MADE IN ESTABLISHING THE CHEMICAL NATURE OF NATURALLY OCCURRING COMPOUNDS, AND MANY SYNTHETIC PREPARATIONS HAVING VITAMIN K ACTIVITY HAVE BEEN PREPARED. SINCE FURTHER EVIDENCE OF THE THERAPEUTIC VALUE OF VITAMIN K PREPARATIONS IS ALSO ACCUMULATING IT SEEMED DESIRABLE TO HAVE A FURTHER REVIEW OF THIS SUBJECT. THE FOLLOWING PAPER HAS BEEN PREPARED BY THE AUTHORS AT THE REQUEST OF THE COUNCIL, AND THE COUNCIL HAS AUTHORIZED ITS PUBLICATION. DURING THE PAST FEW MONTHS THE COUNCIL HAS CONDUCTED EXTENSIVE CORRESPONDENCE RELATING TO THE ADOPTING OF A SUITABLE NONPROPRIETARY NAME FOR VITAMIN K. NAMES WHICH ARE ACCEPTABLE TO THE COUNCIL HAVE BEEN PROPOSED BUT THE COUNCIL IS NOT PREPARED TO MAKE A DEFINITE RECOMMENDATION UNTIL CERTAIN MATTERS RELATING TO PRIORITY HAVE BEEN SETTLED.

PAUL NICHOLAS LEECH, Secretary.

SUPPLEMENTARY REPORT ON VITAMIN K

ALBERT M. SNELL, M.D.

AND

HUGH R. BUTT, M.D.

ROCHESTER, MINN.

In April 1939 a report on the sources, nature and clinical use of vitamin K was prepared by one of us (Snell¹) at the request of the Council on Pharmacy and Chemistry. Since the publication of this report, attention has been called to inaccuracies in the matter of defining a unit of the vitamin. Certain investigators have also questioned some of the statements made with regard to the fundamental causes of deficiency in prothrombin, the methods of recognizing them and the means of dealing with them. This supplementary report has been prepared in an effort both to clarify these matters and to bring up to date the present knowledge of the chemical nature of the vitamin.

DEFINITION OF A UNIT

The Dam unit of activity as defined in some detail in an article by Dam and Glavind² refers to a special preparation of dried spinach, to which a value of 500 units per gram has been arbitrarily assigned. Two mg.

From the Division of Medicine, the Mayo Clinic.

1. Snell, A. M.: Vitamin K: Its Properties, Distribution and Clinical Importance: A Preliminary Report, J. A. M. A. 112:1457-1459 (April 15) 1939.

2. Dam, Henrik, and Glavind, Johannes: Determination of Vitamin K by the Curative Blood-Clotting Method, Biochem. J. 32:1018-1023 (June) 1938.

of this product therefore constitutes one unit. When 2 mg. (1 unit, not 1 mg. as was incorrectly written in the earlier report to the Council) of this standard preparation per gram of body weight is given daily to a highly K-avitaminous chick on three successive days, normal blood clotting is obtained.

Personal communications with Dann³ indicate that her unit of vitamin K is the amount of material, based on a standard of known potency, which when administered to chicks daily will bring about a coagulation time of the blood equal to that produced by the reference standard under the conditions of the test. The reference standard is a special extract of alfalfa which has been shown to be stable over a long period.⁴

Other investigators, including Ansbacher,⁵ have attempted to establish a definition of a unit of vitamin K. Ansbacher's unit is established as "the minimum amount [of vitamin K] necessary to render the blood clotting time of the vitamin K-deficient chick, weighing 70 to 100 Gm., normal within six hours after administration." One of Ansbacher's units is equivalent to 20 Dam units. Thayer and his associates⁶ define a unit of vitamin K as "that quantity of vitamin [K] which produces a clotting time of ten minutes or less in 50 per cent of a group of ten or more chicks which has been fed for the fourteen days immediately following receipt from the hatchery on a diet practically devoid of vitamin K."

Almquist and his associates⁷ have also presented a method of assay of vitamin K, showing that "the reciprocal of the blood clotting time is a simple linear function of the logarithm of the level of the vitamin K level in the ration." Obviously, there is not complete agreement among these investigators working in the same field of biology as to the manner of defining a unit or as to the best methods of assay. While freely admitting the inadequacies of this definition of the unit in the report prepared for publication by the Council on Pharmacy and Chemistry, we are of the opinion that any attempt arbitrarily to establish such a unit of the vitamin is unlikely to suit all investigators. Indeed, it would seem wise to postpone consideration of units, since exact and final knowledge of the chemical structure of substances exhibiting antihemorrhagic activity now is close at hand.

THE CHEMICAL NATURE OF VITAMIN K

In the earlier report to the Council,¹ three of the earlier studies designed to accomplish the purification and isolation of the vitamin were cited. In the light of subsequent developments, these earlier reports can now be omitted from consideration. Recently Almquist and Klose⁸ have prepared a choleic acid derivative, which is a yellow, crystalline substance with a melting point of 186 C. Vitamin K can be separated from this material as a viscous, slightly pigmented oil. Cohn and Schmidt⁹ have shown this preparation to be most effective in increasing low prothrombin values in rats that have biliary fistulas. Dam and his collaborators¹⁰ also

have recently prepared, by a process of molecular distillation and chromatographic methods, a constant product of high purity which they believed to be pure vitamin K. The material, which is a clear yellowish oil, contains carbon, hydrogen and oxygen and is nitrogen free. Elementary analysis has indicated the presence of two atoms of oxygen in the molecule; a tentative composition of carbon 82.2 per cent and hydrogen 10.7 per cent has been established. This material is said to be extremely potent on biologic assay, containing about 20,000,000 Dam units per gram.

In an earlier report the prediction was made that several closely related substances having antihemorrhagic properties were likely to be found in crude extracts of alfalfa or putrefied fish meal. It is in investigations of the type suggested by such a prediction that developments of great importance are now taking place. In May 1939 McKee and his associates¹¹ reported the isolation of vitamins K₁ (from alfalfa) and K₂ (from putrefied fish meal) and presented evidence to indicate a quinoid structure for these vitamins; further work has substantiated these preliminary statements.¹² Almquist and Klose¹³ recently have reported that phthiocol (2-methyl-3-hydroxy-1,4-naphthoquinone) possesses physical and chemical properties similar to pure vitamin K.^{13a} Phthiocol was first isolated by Anderson and Newman¹⁴ from the pigment of *Mycobacterium tuberculosis*; its synthesis was announced in 1934.¹⁵ It has been shown by Almquist and Klose¹³ that phthiocol is effective in preventing hemorrhagic diathesis in chicks subsisting on a K-deficient diet when phthiocol is given at 20 mg. per kilogram of diet. They have also suggested that phthiocol is the simplest member of a homologous series of antihemorrhagic substances. Later these investigators¹⁶ reported that the antihemorrhagic activity of phthiocol lay somewhere between that of methyl naphthoquinone and hydroxy naphthoquinone. Their study indicated that the methyl group was functionally important whereas the hydroxyl group seemed to reduce activity. They agreed that the activity of phthiocol is lower than the more complex form of vitamin K existing in alfalfa; Ansbacher and Fernholz¹⁷ were of a similar opinion. The use of phthiocol in the correction of prothrombin deficiency in chicks has been studied in detail by Almquist and Klose;¹³ clinical studies with this material will be mentioned later in this report.

13a. It has been thought that phthiocol owes its activity to some impurity, presumably 2-methyl-1,4-naphthoquinone. However, the most recent report of Fernholz and Ansbacher (Vitamin K Activity of Synthetic Phthiocol, *Science* **90**: 215 (Sept. 11 1939)) indicates that even after purification, synthetic phthiocol has antihemorrhagic properties. In this same report they also noted the powerful curative effect of 2-methyl-1,4-naphthoquinone in chicks deficient in vitamin K.

Recently Thayer and his associates,¹⁸ as well as MacCorquodale and his co-workers,¹⁹ working in Doisy's Laboratory at St. Louis University Medical School, have found 2-methyl-1,4-naphthoquinone the most active compound studied, but when this compound was compared with the natural vitamins K₁ and K₂ its activity was relatively insignificant. They believed the structure of the vitamin K₁ molecule to be 2-ethyl-3-phytyl-1,4-naphthoquinone. Fieser and his co-workers²⁰ suggested that the structure of K₁ was 2,6 (?) -dimethyl-3-phytyl-1,4-naphthoquinone (or the 2-mono-methyl compound) and that that of vitamin K₂ was 2,3-difarnesyl-1,4-naphthoquinone.

Further work by Binkley, MacCorquodale, Thayer and Doisy²¹ at St. Louis University Medical School has confirmed, through synthesis, the structural formula of vitamin K. Their experiments demonstrate conclusively that the structure of vitamin K₁ is correctly represented by the formula 2-methyl-3-phytyl-1,4-naphthoquinone. This work has been further confirmed by Fieser, Campbell, Fry and Gates,²² who described the synthesis of vitamin K₁.

Since the activity of 2-methyl-1,4-naphthoquinone is approximately equal to that of pure vitamin K₁, Thayer, Binkley, MacCorquodale, Doisy, Emmett, Brown, and Bird²³ have suggested that it be adopted as a basic standard for assay of vitamin K. The compound does have desirable qualities for standardization in that it can be obtained readily in a satisfactory state of purity, has a definite melting point for characterization and, when protected from excessive exposure to light, is readily stable. They suggested that by adopting this substance as the standard for assay the unit could then be defined in terms used by the League of Nations committee as the specific vitamin K activity of 1 microgram of pure 2-methyl-1,4-naphthoquinone.

THE GENERAL CLINICAL CAUSES OF DEFICIENCY IN PROTHROMBIN

In the earlier report the methods of Quick, of Dam and his co-workers and of Warner, Smith and Brinkhous were mentioned. The method of Quick has found favorable reception in this country and is now widely used as a routine method for determining deficiency in prothrombin in hospital practice; Dam and Glavind still prefer their modification of Fisher's method. Zifren and his co-workers²⁴ have recently described a simple "bedside" method of comparing the clotting time of normal blood to that of the specimen in question after thromboplastin has been added to each. The unknown is expressed in percentage of the normal.

The principal clinical points to be emphasized here are: (1) that whichever of these methods for deter-

mining deficiency in prothrombin is to be employed most effectively depends somewhat on the experience and the facilities of the physician concerned; (2) that the nature of prothrombin is unknown and that all methods of measurement thus far proposed are open to some objections on this score, and (3) that the simpler the method used, the more likely it is to be used as frequently as is necessary in the care of patients who have actual or impending hemorrhagic tendencies.

THE GENERAL CLINICAL CAUSES OF DEFICIENCY IN PROTHROMBIN

Several investigators have reported a number of conditions in which there exists a deficiency of prothrombin which can be corrected by the administration of vitamin K. Hypoprothrombinemia among human beings apparently may occur in any of the following circumstances:

1. After ingestion of a diet inadequate in vitamin K. Hypoprothrombinemia from this cause is being reported by Kark and Lozner;²⁵ their patients responded adequately to the administration of vitamin K. This clinical observation is well supported by the experimental production of low blood values for prothrombin in rabbits (Dam and Glavind²⁶), in rats (Greaves²⁷), and in mice (Murphy²⁸) following the administration of diets deficient in vitamin K.

2. In newborn infants. Waddell and Guerry²⁹ have recently reported that among newly born infants there is not infrequently a deficiency of prothrombin which responds to the administration of vitamin K by mouth. The mechanism of this type of prothrombin deficiency is not entirely clear, although it is suggested that such a deficiency might be corrected by the administration of vitamin K to mothers before delivery.

3. With inadequate intestinal absorption. This may result from: (a) lack of bile in the intestine due to a poor secretion of bile salts, to (b) an obstruction of the bile ducts from any cause, or to (c) inadequate absorption due to various intestinal lesions, including short-circuiting surgical procedures and intestinal obstruction. All these various factors have been demonstrated among patients by Osterberg and us³⁰ and by Clark and his associates.³¹ It has likewise been demonstrated that severe diarrheal diseases, such as ulcerative colitis, sprue or celiac disease, may result in a deficiency in prothrombin.

4. Injury to the liver. There is considerable evidence, clinical and experimental, to indicate that the liver plays an active part in the formation of prothrombin. It must be admitted that some of this evidence is largely circumstantial. Smith, Warner and Brinkhous³² have shown

that in dogs whose livers have been injured by acute intoxication with chloroform there develops a deficiency in prothrombin with a definite hemorrhagic tendency. More recent work by Warner³³ indicates that extirpation of a large portion of the liver in rats results in a marked decrease in the concentration of prothrombin in the plasma, thus supporting the belief that the liver is perhaps directly concerned in the manufacture of plasma prothrombin. Warren and Rhoads³⁴ have performed complete hepatectomies in dogs and have noted a rather rapid decrease in the concentration of prothrombin in the plasma following this procedure. They concluded that the liver is essential to the formation of prothrombin in the dog. Their work further supports the contentions previously mentioned.

Clinically we³⁵ have seen, as has Warner,³⁶ that primary hepatic disease, such as cirrhosis, atrophy or chronic hepatitis, is not infrequently accompanied by hypoprothrombinemia. We have encountered several patients having primary hepatic damage who, in spite of an adequate diet and ingestion of adequate amounts of bile salts or bile by mouth, continued to exhibit a pronounced deficiency in prothrombin. An occasional patient in such a group as this will not respond even to large doses of concentrates of vitamin K administered orally with bile salts or given intramuscularly. These clinical observations again tend to support the thesis that the liver is intimately connected with the whole process of prothrombin formation.

These recent developments show that there are apparently several conditions other than those previously reported in which a deficiency of prothrombin may be encountered. The conclusion seems justified that at least four basic factors appear to be necessary in the prevention and control of hypoprothrombinemia that may occur among human beings, namely (1) the presence of bile of normal composition in the intestinal tract; (2) a diet containing the vitamin itself or materials from which it can be formed; (3) presence of a normal absorptive surface in the small intestine, and (4) a liver which is capable of performing adequately the synthesis of prothrombin.

METHODS OF ADMINISTRATION

Methods for the oral administration of vitamin K and bile or bile salts in the treatment of deficiency in prothrombin have been described in recent papers in *THE JOURNAL*.³⁷

Dam and his co-workers have shown that definite beneficial effects on patients having a deficiency in prothrombin follow the intramuscular administration of emulsions of vitamin K. At the time of our earlier report we were not able to reproduce the results of Dam and his co-workers by using preparations of vitamin K available to us; we have since fully confirmed their observations. The response to intramuscular administration is distinctly less rapid than that which follows oral administration. Also it is not apparent that any great advantage accrues to the patient by the

intramuscular procedure except when the jaundiced individual in question is, for one reason or another, unable to take or absorb the vitamin by mouth. The possible advantage of long-continued slow absorption of injected material must be mentioned. The peroral method of administration has sufficed for the care of the great majority of patients having a deficiency in prothrombin, and in our opinion it is still the best method for general use.

In the treatment of patients who have hypoprothrombinemia, circumstances occasionally arise in which the intravenous administration of vitamin K might be desirable. However, we have felt that to administer intravenously the preparations of vitamin K available to us in the past would have entailed considerable danger to the patient. Recently Dam³⁸ has administered emulsions of vitamin K intravenously to human beings without the occurrence of untoward reactions. The recent report by Almquist and Klose that phthiocol exhibited antihemorrhagic properties suggests that this compound might be well adapted for parenteral administration and thus might be useful clinically. Smith and his associates³⁹ of the University of Iowa made a brief report in a note at the conclusion of their recent article in *THE JOURNAL* concerning the intravenous administration of phthiocol to one patient who had obstructive jaundice, following which there was an increase in the concentration of prothrombin in the plasma.

We have recently reported the intravenous administration of phthiocol to a number of patients having hypoprothrombinemia.⁴⁰ To one individual, 100 mg. of the material was administered by mouth together with bile salts, with a resulting elevation in the concentration of prothrombin as measured by the method of Warner and his associates. We have also administered intravenous preparations of phthiocol in doses of from 25 to 50 mg. to nine patients having hypoprothrombinemia. These patients had obstructive jaundice or primary hepatic injury, and one patient had intestinal obstruction. In each instance following the administration of phthiocol there was a reduction in the prolonged Quick prothrombin clotting time.⁴¹ No untoward reactions were noted following the administration of phthiocol in any instance. Whether or not the intravenous use of preparations exhibiting antihemorrhagic activity will replace the oral methods now in general use must await further clinical developments.

CONCLUSIONS

Various phases of the chemical, physiologic, biologic aspects and the clinical usefulness of vitamin K are developing so rapidly that a number of the views expressed in the present report may require modification within a comparatively short time. Therefore it would seem wise at the present moment to withhold any dogmatic statements until the recently developed chemical products exhibiting vitamin K activity have been studied more extensively from biologic and clinical standpoints.

41. Since this report was submitted to the Council a synthetic compound, 1,4-dihydroxy-2-methyl-3-naphthaldehyde, has been supplied to us by Dr. E. A. Doisy of St. Louis. When administered intravenously in doses of from 5 to 10 mg. this preparation has been effective in reducing elevated prothrombin times as calculated by the Quick method, in cases of obstructive jaundice. Ten patients have been treated and no untoward reactions have been noted.

SATURDAY, DECEMBER 2, 1939

The Platform of the American Medical Association

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

8. Expansion of public health and medical services consistent with the American system of democracy.

HEREDITY IN INFECTIOUS DISEASES

Since 1923 the role of heredity in infectious diseases has been studied by Webster,¹ who investigated the behavior of these diseases in mice. Common practice shows, he says, that if a batch of mice is given an injection of a virulent agent by some artificial route the great majority die within a few hours. Observed differences in survival rates under the influence of less virulent agents, smaller doses and like variations have heretofore been attributed solely to uncontrolled errors of technic. It was shown in 1923 that batches of laboratory bred mice exposed to infectious agents in a way simulating nature differed from batches of uncontrolled mice in responding as a group in a relatively predictable manner. Further, by varying the diet a definite individual difference was demonstrable. Progeny from parents which died early from test infection with mouse typhoid were more susceptible than those from parents which survived such test infection. This observation was regarded as proof that parents which died early were actually more susceptible by inheritance than those which survived. From highly susceptible parents, lines of varying high susceptibility to mouse typhoid and to encephalitis virus were developed through selection and brother-to-sister inbreeding. Susceptibility remained unchanged for twelve generations in lines in which it was greatest at the outset, while, in lines in which it was intermediate, susceptibility increased through selection.

The same circumstances held true for resistant lines. The crossing of highly susceptible with highly resistant lines resulted in percentage mortalities approximately like those which would be expected on the basis of a single factor type of mendelian inheritance for resistance to mouse typhoid and to encephalitis virus as well. Resistance proved dominant in each instance. It was shown, however, that the amount of inherent resistance displayed by an individual to one infectious agent could not necessarily be taken as a measure of resistance to another infectious agent. Under conditions in which mouse typhoid is allowed to spread naturally among herds of mice composed of different proportions of individuals of innately high or low susceptibility, from 85 to 95 per cent of the innately susceptible succumbed to the infection, in contrast to less than 5 per cent of the innately resistant. The surviving population becomes composed, therefore, largely of individuals known at the outset to be innately resistant, although these are nevertheless likely to become infected and to harbor mouse typhoid bacilli. When new individuals, chiefly of innately resistant stocks, are added to surviving populations, mouse typhoid spreads to both resistant and susceptible. Mortality from the infection, however, is again almost exclusively limited to susceptible recruits and is sporadic or epidemic according to the numbers and proportions added.

1. Webster, Leslie T.: *Heredity in Infectious Disease*, J. Heredity 30: 365 (Sept.) 1939.

Assuming the fact that inherited factors are of basic importance in determining the character of infection in both the individual and the herd, present interest is principally focused, Webster says, on the methods of modifying the expression of these factors through environmental ones. Of those tested so far, diet is the most important and has been proved capable of changing susceptibles to resistants and vice versa. Indeed, epidemics may be started and terminated merely by altering the dietary factors.

Even if only a few of the implications of these experimental studies can be applied to human conditions, the effect on medical thought may be revolutionary. The part which inherited disposition in resistance to infectious disease may play is highly important. A significant element may also be introduced into the understanding of many phases of human epidemiology. Finally the alteration of what appears to be a hereditary character by such environmental factors as diet may exert an unprophesiable effect on the course of many human activities. Indeed, even though the results of these studies cannot as yet be applied to man, they should serve to stimulate new lines of thought.

TRANSFUSION OF PRESERVED BLOOD

The obvious advantages of storing blood for transfusion have led to the adoption of "blood banks" by many large hospitals throughout the country.¹ With grouped and serologically tested blood always available, precious time is saved in the emergencies that so often arise in accident and surgical cases. In time of war this becomes even more important than in civil life. In addition there is a large financial saving, since there is less need for professional donors. During the past two years preserved blood has probably been used for thousands of transfusions.

While the transfusion of preserved blood has definite advantages, there are also certain limitations to its use. Blood is a living fluid, and processes tending toward autolysis continue even when it is stored at low temperatures *in vitro*. It becomes important to establish, therefore, the maximum length of time during which such blood can be kept before use, and in this there seems to be no unanimous agreement. Two methods of approach have been used, namely the study of the changes which occur in stored blood and the results of the transfusion of such blood.

Blood stored *in vitro* keeps best at temperatures between 0 and 5 C. But even at low temperatures the platelets and leukocytes break down within a period of only a few days. According to Rhoads and Panzer² the prothrombin time of blood stored even for periods of from one to two days is greatly prolonged, and therefore the consensus is that stored blood is not as

useful as fresh blood in hemorrhagic diseases. Most of the studies have centered about the behavior of the erythrocytes, since these after all are the most essential elements in the treatment of hemorrhage and anemia. A progressive increase in the fragility of the erythrocytes has been noted as the storage time is lengthened, but manifest hemolysis is not evident until the end of the second week. Scudder and his co-workers³ have observed a marked shift of the potassium ions from the red blood cells into the plasma with blood kept more than five days and feel therefore that such blood should not be used for transfusion. It seems doubtful, however, that the amount of free potassium is sufficient to cause toxic symptoms.

With regard to results of transfusion, it has been found that there is no difference in the incidence of untoward reactions provided the blood has not been kept too long. At the Cook County Hospital¹ the time limit set for the storage of blood is ten days, since a significant increase in the number and severity of reactions was noted when the blood had been kept for longer periods. From another angle, Schaefer and Wiener⁴ have recently attacked the problem by tracing the fate of the transfused erythrocytes in the patient's circulation. With a method similar to that used by Ashby, who showed that when fresh blood is transfused the erythrocytes persist in the circulation for periods up to three or four months, these authors found that, when blood less than five to eight days old was transfused, the period of survival was not significantly different from that of fresh blood. However, in four cases when blood stored for periods ranging from ten to twenty days was used, the cells could be detected in the patient's circulation only up to from one to three weeks. In most of these cases the number of transfused erythrocytes dropped rapidly, and this was accompanied by the appearance of an icteric tint in the patient's serum. This could be demonstrated regularly after the injection of blood more than from eight to twelve days old, provided the patient's serum was examined at the proper time.

These investigations indicate that blood more than from a week to ten days old is not equivalent to fresh blood. Indeed, with blood that is too old there is even some danger of hemoglobinuria and serious symptoms such as are known to result from the transfusion of incompatible blood.

When the available data are taken into consideration, it is evident that the transfusion of preserved blood has acquired an important role. This is a great change in attitude from the opinion held less than two decades ago, when the transfusion of citrated blood even when fresh was looked at askance. However, there are defi-

nite limitations to the use of stored blood which should be taken into account. Pending further investigation, a safe limit to set for the use of such blood would be between five and ten days. Perhaps by improving the method of storing blood it may be possible to extend the time limit.

Current Comment

NATIONAL PHYSICIANS' COMMITTEE FOR THE EXTENSION OF MEDICAL SERVICE

An item appears in the Organization Section in this issue of *THE JOURNAL* telling of the organization of the National Physicians' Committee for the Extension of Medical Service. This committee is headed by a group of physicians, many of whom are widely known for their work in the American Medical Association. The organization is not, however, officially connected with the American Medical Association itself. Information elicited from the officials of the National Physicians' Committee indicates that this group has been organized voluntarily to carry on education of the public regarding the extension of medical service and preventive medicine. Their work is of the nature of public relations activities. The National Physicians' Committee is in a position to accept contributions from industrial and other organizations in order to aid this campaign. The American Medical Association itself has not in the past and does not now accept such contributions. Officials of the organization state also that it is their intent to include in the various subcommittees of the main organization groups of dentists, nurses, hospital executives, pharmacists and all of the other special groups in the field of medicine.

NORMAL BLOOD PRESSURE

Much difference of opinion prevails as to what constitutes normal blood pressure; obviously the pressure can vary widely among different individuals of the same age groups or in the same individual at different ages and under altered circumstances. A recent study of this subject by Robinson and Bruer¹ has tended to revise downward generally accepted normal blood pressure levels. These authors made an exhaustive statistical study of 7,478 men and 3,405 women, all relatively sedentary in their occupations, selected at random in the Chicago area and economically selected by being able to afford insurance policies of \$1,000 or more. Eighty-six per cent of the men had systolic blood pressures of between 90 and 130 mm. of mercury, 54 per cent between 100 and 120, 6 per cent below 100 and 25 per cent below 110. Of the women, 89 per cent had systolic pressures of between 90 and 130, 56 per cent between 100 and 120, 18 per cent below 100 and 44 per cent below 110. The greater tendency to low blood pressures in the women was found in the younger age groups. Up to the age of 60, half or more

of the men had systolic pressures lower than 120, and that of about three fourths never rose above 130. The indications are, they say, that hypertensive men are those who have systolic pressures above 120 appearing at an early age. The authors also presented the continuous blood pressure history of 500 apparently well men examined annually over a period of about ten years. Blood pressures consistently low did not show as much change from year to year as those consistently high. Persons with systolic pressures below 120 rarely changed their level in the direction of a steady rise. In the third phase of this study Robinson and Bruer pointed out that deviations from physiologic norms represent the most accurate check on degenerative processes at work and of potential longevity. If the upper limits of normal pressures are set at 120 systolic and 80 diastolic, a definite parallelism could be observed with the actuarial figures of insurance companies. With a rise in blood pressure there was an abrupt rise in death rate. Pressures, they conclude, of 130 to 144 systolic and diastolic pressures of over 80 cannot be regarded as normal. Accordingly, the popular notion that low blood pressure is a disease and moderately high pressure normal and safe is fallacious. On the contrary, they say, longevity is based on three physiologic levels: low weight, low pulse rate and low blood pressure.

THE MEDICAL SOCIETY OF DELAWARE

One hundred and fifty years ago, twelve days after George Washington took the oath of office as first President of the United States, a group of twenty-seven physicians brought into being the Medical Society of Delaware, the third oldest state medical society and the second oldest medical corporation in the United States. At a recent banquet in celebration of this occasion the speakers were Hon. Richard C. McMullen, governor of Delaware, Dr. Rock Sleyster, of Wauwatosa, Wis., President of the American Medical Association, Dr. L. A. H. Bishop, past president of the Medical Society of Delaware, and Mrs. Rollo K. Packard, of Chicago, National President of the Woman's Auxiliary to the American Medical Association. The Delaware Academy of Medicine exhibited books, instruments, photographs and other articles belonging to the early members of the Medical Society of Delaware. Furthermore, the president of the society, Dr. M. I. Samuel, prepared a special book in connection with the sesquicentennial celebration in which are brief accounts of meetings of the society from year to year, notations on papers read before the fellows, a list of the members of the many committees of the society, a historical account of the early organization, excerpts from presidential addresses, biographies and portraits of the society's presidents, short descriptions of the hospitals in the state of Delaware, and records of the health laws and medical practice acts. The cooperation of the Medical Society of Delaware with the state legislature has brought about laws which safeguard the health of that community and insure to the people high standards of medical care.

ORGANIZATION SECTION

THE NATIONAL PHYSICIANS' COMMITTEE FOR THE EXTENSION OF MEDICAL SERVICE

On November 18, in Chicago, a formal meeting of an executive board officially launched a new organization, the National Physicians' Committee for the Extension of Medical Service. At this meeting the following officers were elected: Dr. Edward H. Cary, Dallas, Texas, chairman; Dr. Austin A. Hayden, Chicago, secretary, and Dr. N. S. Davis III, Chicago, treasurer. These officers were given authority to act as a management committee for the new organization.

A central committee of more than 800 physicians is being formed, in which all the states will be represented. Some of those already listed in the central committee include Drs. Howard Morrow, San Francisco; Charles W. Mayo, Rochester, Minn.; Herman L. Kretschmer, Chicago, and Charles Gordon Heyd and Haven Emerson, New York.

The organization is an independent one, not affiliated in any way whatever with the committee sponsored by Mr. Frank Gannett under the management of Dr. Edward A. Rumely or with the so-called Committee of Physicians or with the American Medical Association. The functions will not, it is stated, overlap or infringe on those of existing county, state or national medical organizations. For its finances, this organization depends wholly on voluntary contributions from physicians, dentists, nurses, hospitals, pharmacists and lay groups interested in the maintenance of the private practice of medicine. In literature released by the Management Committee, the reasons for forming this new institution are stated as follows:

Medicine is confronted with two new sets of conditions. On the one hand, widespread unemployment, low farm income, and the continuation of conditions of general depression have made it difficult for an ever increasing number of people to pay for the best medical service and proper hospitalization out of earnings.

On the other hand, there is the trend—worldwide in scope—toward governmental paternalism and the false, suicidal doctrine that the "state" can provide a service and a security that the people cannot otherwise obtain. As related to medicine, the implementing of this concept would effect revolutionary changes in both the practice of medicine and the underlying philosophy

which has given it the dynamic quality that resulted in worldwide leadership.

If the ethical and scientific standards are to be maintained, the independence of American medicine preserved and the public interest best served, American physicians must:

1. Make possible the providing of medical service to the indigent and those in the low income groups, and insure the most widespread distribution of the most effective methods and equipment in medicine and surgery.

2. Assume the responsibility of countering destructive propaganda by familiarizing the public with the facts in connection with the methods and the achievements of American medicine.

The objectives are embodied in a motion, unanimously adopted by the directors:

Resolved, That the National Physicians' Committee for the Extension of Medical Service is a nonprofit, nonpolitical organization for maintaining ethical and scientific standards and extending medical service to all the people . . . and for . . . cooperating with lay and medical institutions and groups, interested in the preservation of national health, to make more generally known the achievements and to safeguard the independence of American medicine.

A broadgauge nationwide educational program has been planned and the preliminary steps have been taken to put it in operation. An effort will be made to familiarize the public with the aims, the methods and the effectiveness of American medicine. It is believed that this will result in generally improving health conditions and will tend to offset propaganda that is altering the point of view of the individual and adversely affecting the status of the physician.

The Executive Board includes Dr. Edward H. Cary, Dallas, Texas; Dr. Austin Hayden, Chicago; Dr. N. S. Davis III, Chicago; Dr. Irvin Abell, Louisville, Ky.; Dr. F. F. Borzell, Philadelphia; Dr. William F. Braasch, Rochester, Minn.; Dr. John A. Hartwell, New York; Dr. Roger I. Lee, Boston; Dr. Alphonse McMahon, St. Louis; Dr. E. H. Skinner, Kansas City, Mo., and Dr. Charles B. Wright, Minneapolis.

Mr. John M. Pratt has been secured as executive administrator. The offices are at 700 North Michigan Avenue, Chicago.

THE A. M. A. PROGRAM

[Editorial from the Providence Sunday Journal, Nov. 19, 1939]

The American Medical Association has come out with a program of principles for solving the nation's health problems without resorting to federal government control and compulsory freedom and corollary responsibility under democracy's looser system. It is seen and keenly appreciated again, as if it were a new discovery, that the free and responsible individual who is the unit of government is a far different person than the man or woman who is the creature of government.

Everybody talks about democracy and the menaces to it these days. Regimentation of life in certain foreign countries induces a wholesome, overdue reexamination of the values of individual freedom and corollary responsibility under democracy's looser system. It is seen and keenly appreciated again, as if it were a new discovery, that the free and responsible individual who is the unit of government is a far different person than the man or woman who is the creature of government.

But it is not so clearly seen that regimentation can come to a people insidiously, in beneficent guise, as well as through the compulsion of a recognized and feared dictatorship; that, for example, the eager pursuit of social objectives which are intrinsically admirable may require dangerous strengthening and extension of the federal power, debilitation of the states as sovereign entities which are closer to the people and further destruction of individual responsibility, self reliance and freedom of action.

To the extent that that occurs democracy is damaged, and it is for that reason that it is decidedly in point to study proposed approaches to the national health problem with the preservation of democracy in mind.

The federal government, from motives of paternalism or bureaucracy, has a well developed penchant for patting the

citizen on the head—extracting money from his pocket, of course, to pay for the gesture. There are some who would now have it wipe his nose and extract some more money, this paternalism being in the form of compulsory sickness insurance. It would further decrease his economic freedom of action, but no thought is given to that. It would further decrease his responsibility and capacity for taking care of himself on his own initiative, and it would alter, perhaps profoundly, his traditional and important relationship to the medical profession, which exists for and because of his needs as a private citizen and human creature rather than as a ward of government. But no thought is given to that, either.

The fact is that the advocates of head patting and nose wiping want, or at least are willing to accept, a socialized nation as the price of paternalism. The battle with them therefore ought to be waged on that front. Health is not the issue; democracy is. As a matter of fact the prime public problem in the United States today is not at all the health of the citizens; the prime problem is the decidedly poor health that the federal government is enjoying. The latter is obese with bureaucracy and ravenously hungry for more taxes to satisfy its self-generated, insatiable appetite. It ought to be put on a programmatic diet before it eats us out of house and home. Is there a doctor in the house?

OFFICIAL NOTES

ANNUAL CONGRESS ON INDUSTRIAL HEALTH

Arrangements have been completed for the second Annual Congress on Industrial Health sponsored by the American Medical Association, which will be held Monday and Tuesday, Jan. 15 and 16, 1940, at the Palmer House in Chicago.

Topics and speakers are as follows:

OPENING SESSION, MONDAY MORNING, 9:45

Report of the Council on Industrial Health.

STANLEY J. SEEGER, M.D., Chairman, Milwaukee.

Vocational Rehabilitation in Relation to Medical Practice and Workmen's Compensation Procedure.

TERRY C. FOSTER, U. S. Office of Education, Washington, D. C.

Industrial Psychiatry and Mental Hygiene.

LYDIA G. GIBERSON, M.D., New York.

Adequate Nutrition for the Industrial Worker.

LELA E. BOONER, Ph.D., U. S. Department of Agriculture, Washington, D. C.

MONDAY AFTERNOON, 2:15

SYPHILIS IN INDUSTRY

Syphilis in Industry with Special Reference to Its Incidence and Relation to Trauma.

EARL D. OSBORNE, M.D., Professor of Dermatology and Syphilology, University of Buffalo School of Medicine, Buffalo.

Syphilis Case Finding in Industry.

ALBERT E. RUSSELL, M.D., Surgeon in Charge, Office of Syphilis Control in Industry, U. S. Public Health Service, Chicago.

Integrating Syphilis Control Between the Industrial and the Private Practitioner.

HAROLD A. VONACHEN, M.D., President, Central States Society of Industrial Medicine and Surgery, Peoria, Ill.

Syphilis and Employment.

HARVEY BARTLE, M.D., Chief Medical Examiner, Pennsylvania Railroad, Philadelphia.

MONDAY EVENING, 6:30

An informal dinner and round table discussion, intended primarily for members of state and county medical society committees on industrial health, will be held. The subject matter for discussion will include problems of organization and plans for future activity.

TUESDAY MORNING, 9:30

PHYSICAL EXAMINATIONS

Objectives of Health Examinations and Their Industrial Applications.

McIVER WOODY, M.D., President, American Association of Industrial Physicians and Surgeons, New York.

The Private Practitioner and Industrial Physical Examinations.

RAYMOND HUSSEY, M.D., Chairman of Committee on Industrial Health, Medical and Surgical Faculty of the State of Maryland, Baltimore.

The Wisconsin Plan for Physical Examinations in Industry:

The Point of View of the Industrial Commission.

HARRY A. NELSON, Director, Workmen's Compensation, Industrial Commission of Wisconsin, Madison, Wis.

Scope and Methods of Industrial Physical Examinations of the Wisconsin Plan.

PAUL A. BREHM, M.D., Chairman of the Medical Subcommittee on Physical Examinations in Industry, Industrial Commission of Wisconsin, Madison, Wis.

TUESDAY AFTERNOON, 2 O'CLOCK

DISABILITY EVALUATION

Hearing Loss—Estimation of Disability.

AUSTIN HAYDEN, M.D., Chairman Consultants on Audiometers and Hearing Aids, Council on Physical Therapy, American Medical Association, Chicago.

Present Status of Estimating Disability from Visual Loss.

HARRY S. GRADLE, M.D., Chicago.

Are Uniform Standards of Disability Evaluation Practicable?

EARL D. MCBRIDE, M.D., Oklahoma City.

Critique of Disability Evaluation.

HENRY H. KESSLER, M.D., Newark, N. J.

WEDNESDAY, JANUARY 17

On the day following the Congress on Industrial Health, the Chicago Medical Society will conduct all day clinics illustrating practical problems in industrial medicine and traumatic surgery at St. Luke's Hospital in Chicago. These programs are under the direction of Drs. JAMES A. BRITTON and HARRY E. Mock respectively.

On the same day the Chicago Medical Society will conduct a dinner and evening meeting to be addressed by DR. VILRAY P. BLAIR, St. Louis, on "Treatment of Facial Deformities Caused by Injury."

Further details regarding these presentations will be available to registrants at the congress, all of whom are invited to participate in the programs.

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES

The regular fall meeting of the Board was held during the day and evening of November 16 and on November 17.

MEETINGS OF BOARD OF TRUSTEES WITH REPRESENTATIVES OF OTHER ORGANIZATIONS

A joint meeting of the Board of Regents of the American College of Surgeons and the Board of Trustees of the American Medical Association was held, at which numerous subjects of mutual interest were discussed, some of which were referred for further study to a committee to be appointed by the two organizations.

Arrangements were made for a meeting of representatives of the American, Catholic and Protestant hospital associations with the Executive Committee of the Board of Trustees in December and for a meeting of representatives of the American Society of Clinical Pathologists with the Executive Committee in January.

REPORT OF COMMITTEE ON AMERICAN HEALTH RESORTS

A report from the Committee on American Health Resorts recommending that information on health resorts in the United States be assembled was presented and adopted.

REPRESENTATION ON COMMITTEE OF AMERICAN FILM CENTER, INC., AND ON ADVISORY BOARD OF AMERICAN CAMPING ASSOCIATION, INC.

Dr. W. W. Bauer was authorized to accept membership on the Committee on Public Health Films of the American Film Center, Inc., and on the Advisory Board of the American Camping Association, Inc.

PLATFORM FOR HEALTH AND MEDICAL CARE

A platform for the American Medical Association was established indicative of the trend which the Association believes should be followed in the development of health activities and medical care for the people of the United States, and authorization was given for its publication in THE JOURNAL.

NATIONAL PHYSICIANS' COMMITTEE FOR THE EXTENSION
OF MEDICAL SERVICE

Authorization was given for the publication in *THE JOURNAL* of a brief statement relative to the organization and purposes of a committee known as the National Physicians' Committee for the Extension of Medical Service; also for the publication of a communication relative to the Committee of Physicians.

CONFERENCE ON NOMENCLATURE

The Board authorized the calling of a conference early in 1940 for the revision of the Standard Classified Nomenclature of Disease.

OMISSION OF "COL." AFTER THE NAMES OF NEGRO PHYSICIANS
IN AMERICAN MEDICAL DIRECTORY

Instructions were given for the omission of the designation "col." after the names of Negro physicians in the next edition of the American Medical Directory.

VOTE OF THANKS FOR SPACE FOR EXHIBIT OF *HYGEIA*
AT NEW YORK WORLD'S FAIR

A vote of thanks was extended to Dr. Martin A. Couney for the prominent space made available to the Association for an exhibit of *Hygeia* in the Incubator Building at the New York World's Fair, which was visited by 275,000 persons in 1939.

Other business before the Board was concerned with the general affairs of the Association.

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

- December 4—Cole County Medical Society Auxiliary, Jefferson City, Mo.
December 5—Stephens College, Convocation, Columbus, Mo.
December 5—Boone County Medical Society, Columbus, Mo.
December 7—Greene County Medical Society, Woman's Auxiliary, Springfield, Mo.
December 12—Emmett Parent Teacher Association, Chicago.
December 12—Junior Chamber of Commerce, Clinton, Iowa.

DR. MORRIS FISHBEIN:

- December 6—Chamber of Commerce, Duluth, Minn.
December 6—Industrial Safety Conference, Duluth, Minn.
December 11—Mothers' Aid, Chicago.
December 13—Forum and Medical Society, Frankfort, Ky.
December 14—Louisville District Dental Society and Jefferson County Medical Association, Louisville, Ky.

DR. R. G. LELAND:

- December 1—Phi Beta Pi Fraternity, Rush Medical College, Chicago.
December 7-10—American Public Welfare Association, Round Table Conference on Medical Care, Washington, D. C.
December 13—Des Moines Public Forum, Des Moines, Iowa.

DR. ROCK SLEYSER:

- December 5—Medical Society of South Carolina, Charleston, S. C.

DR. PAUL A. TESCHNER:

- December 4—National Committee on Boys and Girls Club Work, 4 H Movement, Meeting, Chicago.
December 6—High School, Peru, Ind.
December 6—Junior High School, Peru, Ind.
December 6—Parent Teacher Association, Peru, Ind.
December 8—Milwaukee County Medical Society Auxiliary, Milwaukee.
December 13—Kane County Medical Society, Elgin, Ill.

DR. NATHAN B. VAN ETEN:

- December 5—South Carolina Medical Association, Charleston.
December 19—The New York County Medical Society, New York.

RADIO BROADCASTS

The seventh season of broadcasting by the American Medical Association over the facilities of the National Broadcasting Company and affiliated stations is now underway with programs scheduled each Thursday at 4:30 p. m. eastern standard time (3:30 central standard time, 2:30 mountain time and 1:30 Pacific time). The program is on the Blue network of the National Broadcasting Company, whose key station is WJZ, New York.

The title of the program is *Medicine in the News*. It is a fast moving, varied, dramatized program based each week on an important news item from *THE JOURNAL*, a state medical journal or other reputable medical publication, or *Hygeia*. Each program will also include the week's medical highlight, which will be either an interesting, amusing or unusual incident, or a series of brief news items taken from current medical literature.

Each week's program will include a question received from a lay inquirer by the American Medical Association. These questions will be of timely, seasonal interest or of universal appeal. The question will be asked at the opening of the program and answered at the close of the program.

It is not possible to state definitely exactly the stations which are taking the program. A list of stations on the Blue network was published in *THE JOURNAL*, October 28. Inquiries should be made of the local station by a committee of the county medical society or the auxiliary. The advantages of the program and its interest to the public should be called to the attention of the station management by the local medical society or auxiliary.

The following radio stations have signified their intention of broadcasting *Medicine in the News*, according to information received from the National Broadcasting Company, November 24:

New England States

WNBC New Britain, Conn.
WLBZ Bangor, Me.

WOMAN'S AUXILIARY

Illinois

The auxiliary to the Bureau County Medical Society met at Spring Valley September 12 at the home of Mrs. M. A. Nix. A donation of \$50 was made to the Crippled Children's Clinic.

The auxiliary to the Coles-Cumberland Counties Medical Society met at Mattoon September 20. Mrs. W. R. Rhodes of Toledo addressed the group on the national and state public health service.

The auxiliary to the Sangamon County Medical Society held an Acquaintance Day Luncheon September 11. The first regular program was held September 25 at the home of one of the members. A review of the September issue of *Hygeia* was given.

New York

The auxiliary to the Nassau County Medical Society met in the Nassau Hospital Auditorium September 20. The auxiliary is cooperating with the County Cancer Committee. At the auxiliary meeting held on September 26 Miss Muriel Bliss, chairman of the Nassau County Committee on Cancer, was guest speaker.

The first meeting of the auxiliary to the Medical Society of Saratoga County was held October 3 in Schuylerville. Addresses were given by physicians on the subjects colds and pneumonia and the importance of hospitals to communities. Auxiliaries to the medical societies of Sullivan County and of Washington County have recently been organized.

Texas

An executive board meeting of the auxiliary to the State Medical Association of Texas was held in Dallas September 21. Mrs. S. H. Watson, Waxahachie, president, reports that forty-one members attended the meeting. —Taylor-Jones Counties Auxiliary will provide one month's maintenance for a needy student at the Texas State College for Women, Denton. —The Central Texas District Auxiliary met in Cleburne recently. Mrs. F. F. Kirby, past president of the state auxiliary,

and Mrs. L. B. Leake, treasurer, gave addresses. The auxiliary was entertained at a joint luncheon with its district medical society at the First Methodist Church. On this occasion Dr. L. H. Reeves, president of the state medical association, was the speaker.

Utah

The board of directors of the auxiliary to the Utah State Medical Association met in Provo October 12. A history of the pioneer physicians of Utah will be prepared by the auxiliary under the direction of Mrs. Walter M. Stookey, past president. The auxiliary will send delegates to the Legislative Council, which meets once each month at the State Capitol in Salt Lake City.

The auxiliary to the Carbon County Medical Society met at the Carbon Country Club October 7. Mrs. Bliss Finlayson of Price will arrange radio programs for the auxiliary.

The auxiliary to the Utah County Medical Society held its first autumn meeting at the home of Mrs. Arnold Robinson in Provo. Plans were made to place *Hygeia* in every grade and high school in the county.

Washington

The auxiliary to the Clark County Medical Society met at the home of Mrs. Charles Otto on the Evergreen Highway overlooking the Columbia River October 3. Plans are being made for the placing of *Hygeia* in reading rooms of public schools.

The auxiliary to the Grays Harbor Medical Society held its September meeting in Aberdeen. Copies of the pamphlet "On the Witness Stand" were distributed.

The September meeting of the auxiliary to the King County Medical Society was held at the Woman's University Club, Seattle. A membership tea was given at the home of Mrs. L. L. Stephens in October, at which time many new members were welcomed. Members of the county *Hygeia* committee have visited outlying communities near Seattle, securing subscriptions for *Hygeia*.

MEDICAL ECONOMIC ABSTRACTS

GROUP HOSPITALIZATION IN WAYNE COUNTY

The Wayne County Medical Society has recommended to its council that the plan offered by the Michigan society for group hospitalization be made available to members of the county medical society.

The Michigan Society for Group Hospitalization was organized by the hospitals of Michigan. It is a nonprofit organization; the members of the board of trustees receive no reimbursement for their services; all employees of the society are on a straight salary basis, and no fees or commissions are paid to representatives. The seventy-eight participating hospitals guarantee the services provided for in the subscriber's certificate—no assessment is possible. The subscriber is assured of hospital service at cost, as the certificate provides that any surplus accruing in the operation of the plan will be returned to the subscribers in the form either of reduced rates or of increased benefits. Ordinarily the plan is available only to groups of ten or more employed people through their place of employment, but special arrangements have been made to make the service available to members of the medical society.

There are no age limits for adults, no physical examination required and no exemptions for chronic conditions. In case of an emergency a subscriber may go to any hospital in the world, and if he holds a ward certificate he will receive \$4.50 a day toward his hospital bill or \$6 a day if he holds a semi-private certificate. The seventy-eight hospitals that guarantee the service are located in forty-one Michigan cities. During the five months that the plan has been in operation 45,000 subscribers have been enrolled.

The county medical society members are now being circulated with an application blank which is also intended as a referendum to determine whether the members approve the plan and if so are willing to enroll.

THE ORDER OF PHYSICIANS IN PORTUGAL

A little more than a year ago the Belgian medical profession was made a legal organization in which every licensed physician is required to hold a membership. Similar legislation was enacted in Germany and Italy, shortly after these became totalitarian states. Portugal has now enacted a similar law, a copy of which appears in the *Presse médicale* for August 12, 1939, page 1239.

The provisions of the Portuguese law creating an "integrated" profession make legal some of the provisions of medical ethics. This is true also in the legislation of the other countries. For example, the physician is required "to respect the customs and local traditions with relation to his patients, and to act with loyalty with regard to his colleagues, and to conduct conscientiously his professional and social duties." All species of advertising, including interviews with the press which tend to attract a clientele, are absolutely forbidden. Pharmacists, chemical laboratories, drug stores or any establishments for the sale of pharmaceutical products and all similar institutions are strictly forbidden to give any sort of medical consultations or prescriptions.

The form of organization, including the management of the order by regular conventions and the form of administration to be set up, are prescribed in the law.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Regional Meeting.—The Northwestern Division of the Alabama State Medical Association will meet in Parrish December 7. At this meeting plaques will be awarded by the Walker County Medical Society to Dr. Charles B. Jackson, Jasper, posthumously, for fifty-three years of distinguished service to the medical profession and to Dr. Hugh W. Stephenson, Oakman, commemorating sixty years of active practice. The speakers will include Drs. Glenn I. Jones, Washington, D. C., on "Railroad Medical Service"; James A. Meadows and Karl F. Kesmodel, Birmingham, "Diagnosis of Cancerous Lesions"; Thompson F. Wickliffe, Jasper, "Virus Diseases"; Sam P. Wainwright, Birmingham, "The Thymus Gland," and Gilbert B. Greene, Birmingham, "Surgical Management of Thyrotoxicosis."

CALIFORNIA

Course for Practitioners.—The University of California Medical School, San Francisco, will offer a course for general practitioners at the University of California Hospital, San Francisco, Jan. 3-6, 1940. The course has been designed to meet the needs of the physician in private practice. Patients, lantern slides and pathologic material will be used to illustrate the discussions.

Society News.—At the annual meeting of the Los Angeles County Medical Association, December 7, Dr. George Franklin Farman will discuss the "History of the Urologic Section and Its Relationship to the Los Angeles County Medical Association," and Dr. Herman L. Kretschmer, Chicago, "The Present Status of Transurethral Resection."—The Los Angeles Society of Neurology and Psychiatry was addressed November 15 by Drs. Clarence W. Olsen on "Injury to the Spinal Cord Incident to Hypodermic Injection," and Samuel D. Ingham, "Neurologic Interpretations of Convulsive Symptoms."—At a meeting of the Los Angeles Society of Ophthalmology and Otolaryngology November 27 the speakers were Drs. Leland R. House on "Cysts in the Maxillary Sinus" and Cyril B. Courville, "Prodromal Syndrome of the Intracranial Extension of Middle Ear and Mastoid Infection."

COLORADO

Society News.—Dr. Robert K. Dixon, Denver, discussed gastro-enterology before the Northeast Colorado Medical Society in Sterling October 12.—At a meeting of the Delta County Medical Society in Delta October 27 Dr. Lawrence L. Hick discussed "Recent Advances in the Treatment of Pneumonia."—The Larimer County Medical Society was addressed in Fort Collins November 1 by Dr. Foster L. Matchett on "Orthopedic Approach to Low Back Pain" and "Internal Fixation of Broken Hips."—The Washington-Yuma Counties Medical Society met in Yuma October 20; the speakers were Drs. Lyman W. Mason on "Pelvic Infections" and Ward Darley Jr. on "Advancement in Diagnosis and Treatment of Cardiac Diseases."—Dr. Henry A. Buchtel, Denver, discussed "Urology and Treatment of Urologic Diseases" at a meeting of the Weld County Medical Society in Greeley November 6.

CONNECTICUT

Society News.—Arne Tiselius, Ph.D., Institute of Physical Chemistry, University of Uppsala, Uppsala, Sweden, discussed "The Application of Electrophoresis Methods to Some Problems in Biochemistry and Medicine" before the Yale Medical Society October 25 under the auspices of the Jane Coffin Childs Memorial Fund for Medical Research.—Dr. Lee E. Farr, New York, discussed "Studies of Nitrogen Metabolism in Children with the Nephrotic Syndrome" before the Yale Medical Society November 8.

Discussions on Pneumonia.—The Connecticut State Medical Society and the state department of health announce a series of programs on the treatment of pneumonia to be given in cooperation with the following medical societies: Bridgeport, Central, Danbury, Greenwich, Hartford, Manchester, Meriden,

New Britain, New London, New Haven, Norwalk, Norwich, Torrington and Waterbury. Dr. Louis H. Nalium, New Haven, opened the series November 16. Other speakers will include:

Dr. Chester S. Keefer, Boston, December 4, in New Britain.
Dr. Russell L. Cecil, New York, December 6, in Hartford.
Dr. Francis G. Blake, New Haven, December 7, in Norwich.
Dr. Blake, December 13, in Danbury.
Dr. John A. Wentworth, Hartford, December 14, in Waterbury.
Dr. Theodore S. Evans, New Haven, December 19, in Greenwich.
Dr. Thomas P. Murdock, Meriden, December 20, in Middletown.
Dr. Blake, December 20, in Norwalk.
Dr. Samuel J. Goldberg, New Haven, January 3, in Meriden.
Dr. Clarence L. Robbins, New Haven, January 3, in Litchfield.
Dr. Blake, January 26, in Manchester.
In Bridgeport March 5, speaker to be announced.

DISTRICT OF COLUMBIA

Society News.—Forest Ray Moulton, Ph.D., permanent secretary, American Association for the Advancement of Science, Washington, D. C., discussed "A Jaundiced Look at the Human Machine" before the Academy of Medicine of Washington October 27.—Dr. Louis H. Clerf, Philadelphia, discussed "Diagnostic Information Derivable from Bronchoscopy" before the naval medical and dental officers on duty in the district at a meeting in the naval medical school November 6.

New Professor of Psychiatry at Georgetown.—Dr. Harry Stack Sullivan, New York, president of the William Alanson White Psychiatric Foundation and faculty chairman of the Washington School of Psychiatry, has been appointed professor of psychiatry and director of the department of psychiatry and neurology at Georgetown University School of Medicine. He succeeds the late Dr. Daniel Percy Hickling, who was a member of the faculty of Georgetown for more than forty years. Dr. Sullivan graduated at the Chicago College of Medicine and Surgery in 1917. He served as associate professor of psychiatry at the University of Maryland School of Medicine from 1923 to 1930 and concurrently as director of clinical research at the Sheppard and Enoch Pratt Hospital, Baltimore.

ILLINOIS

Postgraduate Conference.—Physicians of the seventh, eighth and eleventh councilor districts in cooperation with the Illinois State Medical Society are cooperating in a postgraduate conference to be held in Champaign December 7. The subjects planned for discussion in this conference, which is the second of a new program planned by the state society, include:

The Fundamentals in the Use of Sulfanilamide and Its Allied Compounds in Infection, Dr. Oswald H. Robertson.
Recent Developments in the Treatment of Diabetes Mellitus, Dr. Robert W. Keeton.
Cardiac Emergencies and Their Treatment, Dr. Carlo S. Scuderi.
The Treatment of Athlete's Foot and Other Fungous Infections of the Skin, Dr. Francis E. Seneac.
The Treatment of Common Ailments in Children, Dr. Robert A. Black.
Physical Therapy, Dr. John S. Coulter.
The Management of the Male and Female Climacteric, Dr. James H. Hutton.
The Treatment of Head Injuries, Dr. Harry Mock.
Why, When and How to Immunize, Dr. Harry Leichenger.
Treatment of Common Disorders of the Upper Respiratory Tract, Dr. Francis L. Lederer.

All the speakers are from Chicago.

Society News.—Dr. James H. Hutton, Chicago, addressed the Lawrence County Medical Society at Lawrenceville November 1 on "Classification and Management of the Nervous Hypotensive Patient."—At a meeting of the Sangamon County Medical Society in Springfield November 2 Dr. Vernon C. David, Chicago, spoke on "Carcinoma of the Sigmoid and Rectum."—Dr. Milton H. Kronenberg, Chicago, read a paper before the Winnebago County Medical Society at Rockford November 3 entitled "The General Practitioner's Approach to Industrial Hygiene."—Dr. Benjamin M. Levin, Chicago, discussed "Surgical Diseases of Childhood" before the Bureau County Medical Society in Princeton November 21.—Dr. Irving L. Turow, Peoria, was elected president of the Physicians' Association of the Illinois State Department of Public Welfare at its meeting in Peoria October 12; Dr. George L. Perkins, Manteno State Hospital, was chosen vice president and Dr. Jacob W. Klapman, Chicago State Hospital, was reelected secretary-treasurer.—Dr. Roland M. Klemme, St. Louis, discussed "Surgical Treatment of Parkinson's Disease" before the Champaign County Medical Society, November 9.

Chicago

Society News.—Among the speakers before the Chicago Laryngological and Otological Society December 4 were the following: Drs. J. Allan Weiss on "Mucocele of the Frontal

Sinus"; Robert Henner, "Endaural Complete Mastoidectomy and Attico-Mastoidectomy," and Frank J. Piskiewicz, "Nasopharyngeal Tuberculosis"; all are members of the staff of the Illinois Eye and Ear Infirmary.—A symposium on the treatment of prostatism was presented before the Chicago Urological Society November 30 by Drs. Herman L. Kretschmer, Harry C. Rolnick and Gustav Kolischer.

University News.—Ralph H. Müller, Ph.D., New York, opened a series of six lecture-conferences and demonstrations at the University of Chicago November 6 on "Electronics in Chemistry and Technology."—The Tuberculosis Institute of Chicago and Cook County through the Theodore B. Sachs Memorial Fund has made \$1,000 available to support a study on bronchiectasis and pulmonary abscesses at the University of Illinois College of Medicine. The work is being conducted by Drs. Felix Basch of the department of pediatrics and Paul H. Holinger of the department of otolaryngology.

INDIANA

University Aids City Dispensary.—The Indianapolis Board of Health has approved an arrangement whereby the Indiana University Medical Center, Indianapolis, will give the city hospital dispensary \$10,000 annually to improve the service and the teaching facilities for the school of medicine. Two full time physicians have been named to the dispensary by the university, Drs. Joseph Edward Tether Jr. and August M. Hasevinkle, and two more will be added. With the increased full time staff it is hoped to make unnecessary the return visits by patients to the dispensary. The staff also will be able to treat the patients more rapidly by systematizing appointments. For its assistance, the medical school will be compensated by improved and increased teaching facilities in the dispensary for medical students.

Society News.—Dr. James A. Britton, Chicago, discussed "Medicine in Industry" before the Indianapolis Medical Society October 24. At a meeting October 31 the speakers were Drs. Ethelbert R. Wilson on "The Coroner's Role in Medico-legal Investigation"; John T. Day, "Causes of Chronic Gonorrheal Infection," and Verne K. Harvey, "The Epidemiology of Rocky Mountain Spotted Fever."—At a meeting of the Fountain-Warren Counties Medical Society in Kingman in October Dr. James O. Ritchey, Indianapolis, discussed goiter.—The Fort Wayne Medical Society was addressed October 3 by Drs. Lester L. Eberhart, Angola, on "Treatment of Hip Fracture by Internal Fixation"; Max M. Gitlin, Bluffton, "Undulant Fever," and Thomas O. Dorrance, Bluffton, "Scurvy in Infants."—Drs. Matthew Winters, Indianapolis, and Charles F. Thompson, Indianapolis, discussed "Diarrheas in Infancy" and "Causes of Delayed Walking" before the Shelby County Medical Society in Shelbyville October 4.

KANSAS

Postgraduate Course.—A postgraduate course on syphilis and gonorrhea was started early in November under the auspices of the state board of health and the committee on control of venereal disease of the Kansas Medical Society. It is planned to devote three months to this program so that two lectures each on syphilis and gonorrhea will be presented at a central location in each of the twelve councilor districts. Dr. Arthur D. Gray, Topeka, is the lecturer.

LOUISIANA

Extension Program.—The Graduate School of Medicine of Louisiana State University, New Orleans, inaugurated its 1939-1940 extension program with a symposium on pneumonia before the Franklin Parish Medical Society at Winnsboro November 15. The speakers were Drs. John R. Schenken on "Pathology and Pathogenesis of Pneumonia"; Robert H. Bayley, "Diagnosis and Differential Diagnosis of Pneumonia," and Joseph O. Weilbaecher Jr., "Treatment of Pneumonia."

MARYLAND

Society News.—Dr. John M. McDonald, Baltimore, discussed "Occupational Health Hazards of the Industries in Maryland" before the Medical and Chirurgical Faculty of Maryland October 24.—At a meeting of the Baltimore City Medical Society October 20 Drs. John Sheldon Eastland spoke on "Use of Vitamin K in Obstructive Jaundice" and Nicholson J. Eastman, "Vitamin K and the Newborn."—The Maryland Academy of Medicine and Surgery was addressed October 17 in Baltimore by Drs. Maurice Feldman, Baltimore, on "Aneu-

rysms of the Abdominal Aorta"; Charles W. Maxson, "Early Treatment of Fractures," and J. Bernard Wells, state's attorney, "The Doctor on the Stand."

Dr. Corner to Head Department of Embryology.—Dr. George W. Corner, since 1924 professor and chairman of the department of anatomy of the University of Rochester School of Medicine, Rochester, N. Y., has been appointed director of the department of embryology of the Carnegie Institution of Washington, effective May 1, 1940, on the retirement of Dr. George L. Streeter, who joined the Carnegie staff in 1914 and became director of the department of embryology in 1917. The Carnegie laboratory of embryology is located in Baltimore. Dr. Corner was born in Baltimore. He graduated at Johns Hopkins in 1913. Before going to Rochester in 1924 he served as assistant professor at the University of California Medical School and associate professor at Johns Hopkins. He has been curator of the Rochester Medical Library since 1938, was secretary-treasurer of the American Association of Anatomists from 1930 to 1938 and since early this year has been managing editor of the *American Journal of Anatomy*.

MASSACHUSETTS

Postgraduate Courses.—The Massachusetts Medical Society, cooperating with the state department of health, the U. S. Public Health Service and the Federal Children's Bureau, opened its fall series of medical postgraduate extension courses in October. They will continue at weekly intervals until December.

Harvard Will Not Abandon Dental School.—To correct a rumor that has been circulating, Harvard University announces that plans are not under way to abandon its dental school after seventy years' existence. According to Dr. Leroy M. S. Miner, dean of the dental school, a plan is under consideration involving a new program of dental education, but this does not include the abandonment of the dental school. The usual first year class was accepted this year with a full quota of students and this class will be carried through the entire four years under the present framework, it was stated. According to a release from the university, there is no truth in the statement as applied to the present situation, or to the contemplated new plan, that "All candidates contemplating the study of dentistry must first enroll and qualify by acquiring the degree of doctor of medicine, before entering on the study of dentistry." It was pointed out that whatever new plan is adopted it will still be possible for men to qualify for general dental practice and to satisfy requirements for licensure. The statement that the university is going to discontinue teaching prosthetic and other forms of restorative dentistry and confine itself simply to preparing men for surgery and other specialties is not true. The dental profession may rest assured that any modifications in the curriculum now under consideration will, if put into effect, be expected to elevate the importance of dentistry as a profession and neither to lower its standards nor to diminish its effectiveness, it was stated.

MICHIGAN

Symposium on Poliomyelitis.—The Wayne County Medical Society sponsored a symposium on poliomyelitis at the Detroit Institute of Art November 13. The speakers were:

Dr. Edgar E. Martner, Clinical Aspects and Diagnosis.
Dr. Franklin H. Top, Epidemiology.
Dr. Joseph A. Kasper, Virology and Pathology of Anterior Poliomyelitis.
Dr. Alfred D. LaFerte, After-Treatment from Orthopedic Standpoint.

Hospital Day.—Woman's Hospital, Detroit, sponsored a "hospital day" November 8. The speakers included Drs. George M. Curtis, Columbus, on "The Iodine Metabolism in Thyroid Disease, Emphasizing the Clinical Aspects"; William Boyd, Toronto, Canada, "Some Reasons for the Recent Increase of Bronchial Carcinoma"; John L. McKelvey, professor of obstetrics and gynecology, University of Minnesota Medical School, Minneapolis, "A Study of the Remote Lesions of the Pregnancy Toxemias and Their Clinical Significance"; Arthur H. Parmelee, Chicago, "Practical Points in the Management of the Newborn." Dr. Boyd discussed "Cause and Effect in Disease" at the dinner meeting in the evening.

Changes in Health Officers.—Dr. Fred O. Tonney, Washington, D. C., and formerly with the city health department of Chicago, has been assigned as health commissioner of Delta County during the leave of absence of Dr. Roelof Lanting, Escanaba. Dr. Clifton F. Hall, Topeka, Kan., director of the division of tuberculosis control for the state board of health, will serve as director of the Mecosta-Osceola health department during the absence of Dr. Max C. Igloe, Big Rapids,

who is studying at Johns Hopkins University, Baltimore. While Dr. Lloyd H. Gaston, Sandusky, director of the Sanilac County department of health, is pursuing a course at Yale University during the coming months, Dr. James A. Dolce, Allegan, will serve as acting director.

MINNESOTA

Dr. McQuarrie Goes to Peiping.—Dr. Irving McQuarrie, professor and head of the department of pediatrics at the University of Minnesota School of Medicine, Minneapolis, will go to China about January 1 to serve as visiting professor in pediatrics at Peiping Union Medical School, according to the *Journal-Lancet*. Dr. McQuarrie was granted a leave of absence by the university board of regents and will return to the university next year, it was stated.

Course in Neurologic Roentgenology.—The University of Minnesota, Minneapolis, sponsored a course in neurologic roentgenology at the Center for Continuation Study November 13-15. The speakers included:

Andrew T. Rasmussen, Ph.D., and Dr. Leo G. Rigler, Minneapolis, Anatomy of Brain, Skull and Spine.
Dr. James W. Kernohan, Rochester, Pathology of Tumors of the Brain and Spinal Cord.
Dr. Cornelius G. Dyke, New York, Normal Encephalogram and Ventriculogram.
Dr. John D. Camp, Rochester, Normal and Abnormal Sella.
Dr. Merrill C. Sosman, Boston, Meningiomas and Lesions of the Cerebrum Including Fractures.
Dr. Harold O. Peterson, Minneapolis, Platybasia; Encephalography in Spastic, Mentally Deficient and Epileptic Children.

A symposium on tumors of the brain was presented by Drs. Sosman, John Charnley McKinley, Minneapolis, and Alfred W. Adson, Rochester, and one on protruded intervertebral disks by Drs. Maurice N. Walsh, Ralph K. Ghormley, J. Grafton Love, Rochester, and Dr. Camp. A clinical pathologic conference was conducted by Drs. Dyke, Camp, Peterson, Sosman and Abe B. Baker, Minneapolis.

MONTANA

Personal.—Dr. Enoch M. Porter, Great Falls, has been named vice president of the state board of health, filling the unexpired term of the late Dr. Louis H. Fligman, Helena. —Dr. Patrick E. Kane, Butte, has been appointed a member of the state board of medical examiners for a term to end March 2, 1945. He succeeds the late Dr. John A. Donovan.

NEW YORK

Hospital Superintendents Transferred.—Dr. John A. Pritchard, superintendent of Buffalo State Hospital, Buffalo, has been transferred to the superintendency of the St. Lawrence State Hospital, Ogdensburg, to succeed Dr. Paul G. Taddiken. Dr. Willis E. Merriman, head of Manhattan State Hospital, has been transferred to the Utica State Hospital.

Society News.—Dr. Eugene N. Boudreau, Syracuse, addressed the Onondaga County Medical Society, Syracuse, November 7 on "The Medical and Social Challenge of Alcoholism"; Dr. Robert C. Schwartz reported a case of Laurence-Moon-Biedl syndrome (blindness of pituitary origin). —Drs. Edward S. and John Van Duyn II addressed the Syracuse Academy of Medicine November 21 on "Pulmonary Atelectasis Following Severe Trauma" and Clayton A. Sayers, D.D.S., on "The Relation of the Physician to Orthodontia."

Health Supplement.—The second annual health section of the Nassau *Daily Review-Star* was published October 31. All the material in the supplement, which consisted of forty pages in tabloid style, was approved before publication by the Nassau County Medical Society. The first article in the section described in detail the organization setup and activities of the American Medical Association. One of the other important articles dealt with the National Health Program and pointed out the position of the medical profession in relationship to the program.

New York City

Society for Study of Syphilis.—The New York office of the U. S. Public Health Service is sponsoring the formation of a Society for the Study of Syphilis for all physicians in the city who are interested in diagnosis and treatment of syphilis. The basic program will be by and for the general practitioner. Informal meetings are planned at which physicians may discuss their problems.

Annual Hospital Campaign.—The United Hospital Fund is conducting its sixty-first annual campaign for funds to meet the needs of the ninety voluntary hospitals that are members

of the organization. The amount needed this year is \$2,462,618, it was announced. Money received in the campaign is distributed through a special committee which allots funds to member hospitals on the basis of free care rendered, special needs and budgetary requirements of their women's committees. The greater part is used to provide free care for the needy.

Dr. Squier Retires.—Dr. J. Bentley Squier, professor of urology, Columbia University College of Physicians and Surgeons since 1917, has retired, the *New York Times* reports. Dr. Squier, 66 years old, took his medical degree at Columbia in 1894 and was professor of genito-urinary surgery at Columbia York Post-Graduate Medical School from 1909 to 1924. He has in recent years been director of the Squier Urological Clinic at Presbyterian Hospital, consulting surgeon to St. Luke's Hospital and consulting urologist to Roosevelt Hospital and the Neurological Institute. He was president of the American Urological Association in 1913 and of the American Association of Genito-Urinary Surgeons in 1919.

Hospital Lecture Series.—The Journal Club of Montefiore Hospital began its lecture season October 5 with an address by Dr. Esmond R. Long, Philadelphia, on "Primary Tuberculosis in the Adult." Dr. John F. Fulton, New Haven, spoke November 8 on "The Hypothalamus," and Dr. Hugh R. Butt, Rochester, Minn., November 30 on "The Use of Antihemorrhagic Substance (Vitamin K) in the Treatment of Hemorrhagic Diathesis Associated with Hypoprothrombinemia." Other lectures that have been announced are:

Drs. Alexander B. Gutman, Clinical and Chemical Aspects of Hyperparathyroidism; and Henry L. Jaffe, Pathology of Hyperparathyroidism, Jan. 17, 1940.
Dr. Virgil H. Moon, Philadelphia, Shock: Its Mechanism, Pathology and Occurrence, February 7.
Dr. Francis Peyton Rous, Viruses and Tumor Causations, February 28.
Dr. Maurice Lenz, Radiotherapy: Its Actions and Medical Application, March 18.

Society News.—Drs. Richard B. Cattell, Boston, and Frank E. Adair addressed the Medical Society of the County of Queens October 31 on "Carcinoma of the Colon and Rectum" and "Treatment of Cancer of the Breast" respectively. —Drs. Herbert M. Evans, Berkeley, Calif., and James B. Collip, Montreal, Canada, addressed the Medical Society of the County of New York October 23 on "Historical Sketch of the Development of Endocrinology" and "Physiology of the Anterior Lobe of the Pituitary Gland" respectively. —A symposium on "Inflammatory Lesions of the Colon" was presented before the New York Surgical Society October 25 by Drs. Carl Eggers, John H. Garlock, William Howard Barber and Wallace B. Murphy. —Drs. Edwin F. Gray and Murray M. Friedman, among others, addressed the New York Roentgen Society November 20 on "Roentgen and Histologic Studies of Calcification in the Spleen" and "Anomalies of the Cervical Spine" respectively. —Drs. Dorothy H. Andersen and Jean R. Oliver addressed the New York Pathological Society November 30 on "Renal Parathyroidism in Childhood" and "The Architecture of the Amyloid Kidney" respectively. —Drs. Frank R. Smith and Oswald S. Lowsley addressed the Harlem Medical Association November 1 on "Cancer in Gynecology" and "Newer Aspects of Urologic Surgery" respectively.

NORTH CAROLINA

Personal.—Dr. Joseph B. Greene, Asheville, was honored at a testimonial dinner November 8 following his retirement from active practice. Dr. Jere E. Cocke was toastmaster and with Drs. John La Bruce Ward and Paul H. Ringer described Dr. Greene's practice of nearly fifty years.

Diploma Lost.—Dr. Milton Carpenter Cobcy, Washington, D. C., who graduated from Duke University School of Medicine, Durham, Sept. 1, 1934, has recently lost his diploma bearing that date. The university has notified the association that a new diploma has been issued to Dr. Cobcy.

New Building to Be Opened at Carolina.—A new Medical Laboratories Building is to be opened December 4 at the University of North Carolina, Chapel Hill, as part of the university's sesquicentennial celebration. The exercises will begin with an address in the morning by Dr. Eli K. Marshall, Jr., Baltimore, on "Medical Research: The Story of Sulfanilamide." In the afternoon Dr. David Riesman, Philadelphia, will speak on "The Making of a Clinician" and Dr. G. Canby Robinson, Baltimore, on "The Application of Medical Science to the Individual." Then will follow an informal tea in conjunction with the inspection of the medical laboratories and the medical dormitory. At a dinner in the evening Dr. Frank

G. Boudreau, executive director of the Milbank Memorial Fund, New York, will speak on "New Health Frontiers." Greetings will be brought to the university and medical school by various alumni and friends.

OKLAHOMA

Society News.—The Tulsa Cancer Society presented a symposium on "Malignancies of the Breast" before the Garfield County Medical Society, Enid, October 26; the speakers were Drs. Ralph A. McGill, Davy L. Garrett, Carl J. H. Hotz, Ivo A. Nelson, Arnold D. Piatt and Harry D. Murdock. All are from Tulsa.

New County Health Officers.—The state health commissioner recently announced appointment of the following new health officers:

Dr. William E. Seba, Leedey, of Dewey County.
Dr. Rudolph H. Dnevall, Miami, of Ottawa County.
Dr. Leo R. Evans, Pryor, of Mayes County.
Dr. James T. McInnis, Muskogee, of Muskogee County.
Dr. O. Hiram Cowart, Bristow, of Creek County.
Dr. Ivan E. Bigler, Ada, of Pontotoc County.

OREGON

Society News.—A program on common eye diseases, sponsored by the Oregon Academy of Ophthalmology and Otolaryngology, was presented before the Multnomah County Medical Society, Portland, November 1 by Drs. Edgar Merle Taylor, Augustus B. Dykman and Frederick A. Kiehle. All are of Portland. Drs. Joyle O. Dahl, and Morton J. Goodman, Portland, addressed the county medical society, Portland, November 15 on "Significance of Serological Reports for Syphilis" and "Prevention and Management of Reactions and Complications of Syphilotherapy" respectively.

PENNSYLVANIA

Postgraduate Meeting at Danville.—The annual fall postgraduate assembly at Geisinger Hospital, Danville, was held October 20 with the following program:

Dr. Charles W. Mayo, Rochester, Minn., Carcinoma of the Right Half of the Colon.
Dr. Arthur W. Allen, Boston, Diagnostic Clinic.
Dr. Russell L. Cecil, New York, Treatment of Pneumonia.
Dr. Harold L. Foss, Danville, End-Results Following Surgical Treatment of Carcinoma of Rectum.
Dr. Roy E. Nicodemus, Danville, Management of Occiput Posterior Positions.

Philadelphia

Tuberculosis Conference.—The annual Philadelphia Tuberculosis Conference, sponsored by the Philadelphia Health Council, the department of public health, the Philadelphia County Medical Society, the Pennsylvania Tuberculosis Society and the Philadelphia Association of Tuberculosis Clinics and other agencies, was held November 14 at the Ritz-Carlton Hotel. At the morning session Dr. Esmond R. Long led a discussion of "Tuberculosis Testing and X-Ray Examinations"; Mrs. Sadie Orr Dunbar, Portland, Ore., president of the General Federation of Women's Clubs, was among the speakers at the luncheon, and Dr. Samuel J. Dickey, director of the tuberculosis division of the state department of public health, Harrisburg, spoke on "Tuberculosis from an Administrative Standpoint."

Pittsburgh

Society News.—Speakers at a meeting of the Allegheny County Medical Society November 21 were Drs. James Leroy Foster on "The Feeding of Infants and Children"; Joseph M. Cameron, "An Autogenous Serum for the Treatment of Menstrual Migraine"; Eben W. Fiske, "Functional Treatment of Fractures and the Combined or Rotating Traumatic Service," and George J. Kastlin, "Effects of Certain Drugs on the Hematopoietic System."

SOUTH CAROLINA

County Society to Celebrate Sesquicentennial.—The Medical Society of South Carolina, which embraces the territory of Charleston County, will celebrate its sesquicentennial anniversary in Charleston December 5 with a historical exhibit and a banquet. The exhibit will be at the Gibbs Art Gallery, showing paintings, books, prints and other material relating to the society's background and its early members. Mayor Henry W. Lockwood of Charleston and Governor Burnet R. Maybank will make addresses of welcome at the banquet, which is to be held at the Francis Marion Hotel. Dr. James J. Ravenel, Charleston, president of the society, will give a historical sketch of the society. Dr. Douglas Jennings, Bennetts-

ville, president of the South Carolina Medical Association, will bring greetings, and Dr. William Weston, Columbia, will present a tablet from the state association. Dr. Nathan B. Van Etten, New York, President-Elect of the American Medical Association, will speak on "An American Health Program" and Dr. Francis R. Packard, Philadelphia, editor of the *Annals of Medical History*, on "Scientific Links Between Charleston and Philadelphia in the Eighteenth Century." The Medical Society of South Carolina was founded Dec. 24, 1789, the first and for many years the only medical organization in the state. The society from its beginning conducted a public dispensary and now owns and operates the Roper Hospital. It also started a collection of books in its early days. In 1822 a medical college was established under the auspices of the society, which conducted the school until it assumed its present status and name, the Medical College of the State of South Carolina. Two medical journals, the *Carolina Journal* and the *Southern Medical and Surgical Journal*, were products of the members of the medical society, according to an announcement. The society still has the original minutes of its meetings from the time of its establishment and the new member today signs his name in the book in which the minutes of the first meeting were written.

TEXAS

Personal.—Dr. Houston H. Terry, formerly of Fort Worth, has been appointed director of the health unit of Cooke County. —Dr. John G. Young, Dallas, has been selected as chief of staff of the Texas Children's Hospital now under construction, it is reported.

Society News.—At a meeting of the Dallas County Medical Society November 9 the speakers were Drs. Charles D. Bussey on "Meckel's Diverticulum—a Pathological and Clinical Study of 155 Cases"; James Howard Shane, "Cold Punch Type Transurethral Prostatic Resection," and Merritt B. Whitten, "Midaxillary Leads in the Electrocardiogram in Infarction and Hypertension."

WASHINGTON

Children's Library Is Memorial to Physician.—A library of children's books is being placed in the Spokane unit of the Shriners' Hospital for Crippled Children as a memorial to the late Dr. Mitchell Langworthy. A fund was collected shortly after Dr. Langworthy's death in 1929 but was saved until a new hospital was built. From this fund a room has been furnished as a library and schoolroom and books have been bought. Dr. Langworthy was chief surgeon of the hospital from 1926 till 1929, when he was shot and killed at the age of 38 by a patient.

Society News.—Dr. Kenneth K. Sherwood, Seattle, addressed the Walla Walla Valley Medical Society, Walla Walla, at its November meeting on "Pathology and Treatment of Chronic Arthritis."—A symposium on cardiac conditions was presented at a meeting of the King County Medical Society, Seattle, November 6 by Drs. Charles E. Watts, who discussed "Cardiac Arrhythmias"; Raymond H. Somers, "Approach to the Cardiac Problem in Children," and Austin G. Friend, "The Heart Patient."—Dr. Frank S. Miller addressed the Spokane County Medical Society, Spokane, November 9 on tuberculosis.

Executives' Conference.—The second annual meeting of the Pacific States Medical Executives' Conference will be held in Seattle December 10. Membership in this conference includes officials of the state medical associations of California, Oregon, Idaho, Washington and Montana. It is expected that representatives may come this year from Arizona, Nevada and Utah. Dr. Harry E. Rhodehamel, Spokane, is president. Matters selected for discussion include: professional societies (the Oregon Plan), medical service plans, malpractice defense problems, prospective health legislation, public relations, prospective public health and practice laws of the Pacific states, postgraduate medical education.

WISCONSIN

County Secretary for Thirty-Five Years.—Dr. Mina B. Glasier, Bloomington, resigned as secretary of the Grant County Medical Society October 31 after serving continuously for thirty-five years. Dr. Glasier was a member of the state board of health for fourteen years. In 1932 she received the Council Award of the State Medical Society of Wisconsin for meritorious service.

Society News.—Dr. David R. Lyman, Wallingford, Conn., was guest speaker at the banquet during the annual meeting of the Wisconsin Anti-Tuberculosis Association in Milwaukee

October 26, giving a memorial address on the late Dr. Hoyt E. Dearholt, for many years executive secretary of the association. Dr. Paul A. Teschner, assistant director, Bureau of Health Education, American Medical Association, Chicago, led a panel discussion on the problem of finding early diagnosis. —Dr. David A. Cleveland, Milwaukee, addressed the Marinette-Florence County Medical Society, Menominee, October 18 on "Head and Spinal Injuries." —Drs. Milton Trautmann, Madison, and Frances A. Cline, Rhinelander, addressed the Oneida-Vilas County Medical Society, Rhinelander, November 2 on "Modern Treatment of Venereal Disease" and "Polio-myelitis" respectively.

GENERAL

Fraternity Convention.—The Phi Delta Epsilon Medical Fraternity will hold its thirty-sixth annual convention at the Waldorf-Astoria Hotel, New York, December 29, 30 and New Year's Eve. About 600 physicians and medical students from this country and Canada will attend. Dr. Morris Fishbein, Editor of *THE JOURNAL*, who is national president, will preside at the sessions.

Help Wanted in Finding Illegal Practitioner.—The prosecuting attorney of the Seventeenth Judicial District of Indiana requests the help of the medical profession in apprehending a man wanted on charges of abortion and illegal practice of medicine. Under the name of Ferdinand Werner, this man has maintained an office in Richmond, Ind., as a pathologist and bacteriologist and has practiced medicine without a license. After many efforts, evidence was obtained recently

to support thirteen charges of illegal practice against him and later charges of abortion were filed. The abortion charge was set for trial in the Wayne Circuit Court November 13, but Werner did not appear, forfeiting a \$2,000 bond. No date has been set for trial on the other charges, but authorities believe Werner will forfeit a \$1,300 bond on these charges. Routine check of the man's fingerprints revealed that he had been convicted of a crime involving moral turpitude in Cleveland in 1923, sentenced to the state penitentiary, from which he escaped in February 1924. Shortly afterward he was employed in the department of pathology and bacteriology at Indiana State University School of Medicine for less than three months and later at the State Hospital for the Insane at Richmond. He was discharged from the latter position when the superintendent learned Werner was not his real name and when his services were found unsatisfactory. He then opened his own laboratory in Richmond. When Werner was convicted in Cleveland he was using the name Sternisa and further inquiry brought out the fact that he had come to the United States under the name of Hribar. The Indiana authorities believe that because of Werner's medical work he will undertake such work again and will have contact with the medical profession. If he is identified, the person making identification is asked to telegraph the information collect to the prosecuting attorney's office at Richmond. The description given by police is as follows: 42 years old; 5 feet 11¼ inches tall; weight 197 pounds; black hair, brown eyes and fair complexion.

Fellowships for Study of Crippled Child.—For the third year the Nemours Foundation will award five or six one-year fellowships for laboratory or clinical studies on the crippled child, to begin on or after July 1, 1940. The term "crippled child" is used in its broadest sense, according to the announcement. The amount of each individual award will be from \$1,000 to \$2,400 and will be determined on the basis of the

previous training of the applicant and the type of research project selected. Application blanks may be obtained from the secretary of the research committee, Dr. Alfred R. Shands Jr., 803 Delaware Trust Building, Wilmington, Del.

Southern Surgical Meeting.—The fifty-second annual session of the Southern Surgical Association will be held in Augusta December 5-7 with headquarters at the Forest Hills Hotel. Among the speakers will be:

- Dr. Waltman Walters, Rochester, Minn., Operative and Postoperative Infections with Special Reference to Air-Borne Bacterial Contaminations.
- Dr. Barney Brooks, Nashville, Tenn., Present Status of the "Radical Operation" for Carcinoma of the Breast.
- Dr. Carrington Williams, Richmond, Va., Hysterical Edema of the Hand and Forearm.
- Dr. Warfield M. Piror, Baltimore, Treatment of Addison's Disease by Implantation of Synthetic Hormone.
- Dr. Thomas D. Sparrow, Charlotte, N. C., Leukoplakic Vulvitis.

At the annual dinner Dr. Hubert A. Royster, Raleigh, N. C., will be toastmaster and Dr. Albert O. Singleton, Galveston, Texas, will deliver the presidential address on "The Surgeon in the Romantic Story of Texas."

Grants for Research in Endocrinology.—Requests to the National Research Council committee for research in endocrinology for aid during the fiscal period from Sept. 1, 1940, to June 30, 1941, will be received until Feb. 29, 1940. In addition to a statement of the problem and research plan or program, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used for administrative expenses. Applications for aid of endocrine research on problems of sex in the narrower sense cannot be given favorable consideration, but the committee will consider support of studies on the effects of hormones on nonsexual functions, for instance, on metabolism. Application blanks may be obtained by addressing the division of medical sciences, National Research Council, 2101 Constitution Avenue, Washington, D. C.

CANADA

Personal.—Dr. Allan C. Rankin, dean of the University of Alberta Faculty of Medicine, Edmonton, has joined the military forces of Canada and Dr. John James Ower has been made acting dean for the present session.

Society News.—Prof. George Grey Turner, London, England, addressed the Academy of Medicine of Toronto, October 12 on "Difficulty in Swallowing." A symposium on the problems related to automobile driving was presented before a joint meeting of the section on preventive medicine and hygiene and the section of neurology and psychiatry by Drs. Kenneth G. Gray on the medicolegal and financial aspects; Robert G. Armour, the neurologic problems, and L. Joslyn Rogers, M.A., the problem of alcohol. —Dr. Howard C. Taylor Jr., Philadelphia, addressed the Academy of Medicine of Toronto November 7 on "Relationship of the Ovarian Hormone to Reproductive Tract Tumors."

LATIN AMERICA

Poliomyelitis in Brazil.—A cable to the *New York Times* October 20 reported that 115 cases of poliomyelitis with six deaths had occurred in Rio de Janeiro. It was announced that the government was taking measures to prevent spread of the disease.

Society News.—Dr. Francisco Ferreira has been elected president of the Society of Ophthalmology and Otolaryngology of Bahia, Brazil, and Dr. Adroaldo de Alencar secretary. Correspondence should be addressed to the president, Pitanguieras 15, Brotas, San Salvador, Bahia, Brazil.

Leprosarium in Cuba.—The cornerstone was laid recently for a new hospital for lepers near Alto Songo, Orienta, Cuba. It is expected that the new institution will be completed by September 1940. It will accommodate 400 patients and will be designed to permit enlargement to care for 400 more. The building will cost about \$380,000.

FOREIGN

Nobel Prizes Awarded.—The 1939 Nobel Prize in chemistry was recently awarded jointly to Prof. Adolph Butenandt of the University of Berlin and Prof. Leopold Ruzicka, Zurich, Switzerland, for their work on hormones. The 1938 chemistry prize was awarded at the same time to Prof. Richard Kuhn of the Kaiser Wilhelm Institute, Berlin, for his work on carotinoids and vitamins. The *New York Times* reported November 11 that Professor Butenandt and Professor Kuhn had declined the prizes because of the ban placed on the Nobel Prizes by the Nazi government.

The Teeth of the Nation Are Bad

The excellent physique of our people and the great improvement in health in recent years, as shown by a lower death rate, infant mortality, maternal mortality and tuberculosis mortality are frequent themes. The good physique of the many thousands of young men called up when this country had recently to adopt conscription is the latest confirmation. But there is one profoundly unsatisfactory condition. Addressing the Public Health Services Congress last year the minister of health said "The teeth of this country are bad; you might almost say they are rotten." In his presidential address to the British Dental Association Mr. T. Walkinshaw laid the blame on our insufficient public dental-health service. We have a school dental service but prevention should begin with the pregnant woman and young children and there is little or no provision for this. Hence the average child enters school with his teeth in an appalling condition. Further, no provision is made for treatment during adolescence. It is curious that in all the discussion of this pressing problem, including that by a leading medical journal, no attempt seems to be made to get to the root of the matter. Why is dental caries so prevalent in civilized countries, while it is absent in people living under primitive conditions? Recent studies in diet appear to furnish an answer. About the middle of the nineteenth century the stone grinders for wheat gave place to steel rollers which remove the whole of the germ and almost all the bran, giving a flour deficient in protein, fat, vitamins A and B and minerals (calcium, phosphorus and iron). In an important book recently published, "The Englishman's Food: A History of Five Centuries of English Diet," the authors (Prof. J. C. Drummond and A. Wilbraham) attribute the appalling prevalence of dental caries to the poorness of white bread in minerals, the reduction in the consumption of milk (with the use of the cheaper forms of condensed milk) and the decline of breast feeding. "Time and again examples can be found of communities with excellent teeth so long as they lived on natural and unrefined foods, but soon after the introduction of highly milled white flour caries appeared."

The Complications of Intranasal Surgery

In a discussion on the complications of intranasal surgery at the Section of Laryngology of the Royal Society of Medicine, Mr. E. D. D. Davis said that a good view of the interior of the nose was essential for operations and that anything in the nature of a blind operation was undesirable. He called attention to four kinds of injuries that had happened in spite of careful technique: perforations and injuries to the roof of the nose or to the cribriform plate, injuries to the orbit and its contents, injury to the optic nerve and injury to the nasolacrimal duct.

Six cases of perforation of the roof of the nose had been recorded and he had seen seven in consultation. They occurred during removal of nasal polypi with forceps or during operation with forceps on the ethmoidal cells for sinus suppuration. The perforation in the removal of polypi was always in the region of the posterior ethmoidal cells, when the forceps was directed upward and backward. It was avoided by directing the point parallel to the roof of the nose. The operator might be unaware that the roof of the nose had been perforated, but escape of cerebrospinal fluid or profuse hemorrhage would be a warning. The patient suffered from shock and after delayed recovery from the anesthetic complained of intolerable headache and was restless and drowsy. Coma rapidly supervened and death occurred within three days, before meningitis had time to develop.

The necropsy showed hemorrhage from the posterior ethmoidal artery into the anterior fossa of the skull. The treatment was the external ethmoidal operation and covering the opening in the dura by a fascial graft. The perforation was inaccessible through the nose.

Hemorrhage into the orbit following perforation of the thin os planum of the ethmoid was the commonest injury. It frequently happened during the ethmoidal operation, particularly on the anterior cells and also in the intranasal frontal sinus operation. The "black eye" was typical and the ecchymosis was maximal at the inner canthus, but if the hemorrhage was considerable the eyeball might protrude. This might be increased by emphysema. All that was necessary in most cases was to keep the patient at rest in the sitting posture, with the eye covered by a pad and bandage. The patient should be forbidden to blow his nose for a few days.

Injury to the optic nerve in ethmoidal operations produced immediate blindness. Davis had been able to collect reports of five cases and had seen two of the patients. One injury was caused by evulsion of the middle turbinal and part of the ethmoid in an operation for polypi. Optic atrophy followed, with permanent loss of sight. Such cases showed the need for care in the use of the forceps for evulsion. It was safer to use cutting or punch forceps kept in a plane parallel to the outer wall of the nose.

Injury to the nasolacrimal duct had been seen on two occasions following an intranasal antral operation. The window made in the nasal wall of the antrum extended into the middle meatus above the attachment of the inferior turbinal, severing the duct. On recovering from the operation the patients complained of blood leaking into the eye. Epiphora and lacrimal obstruction followed. After injection of the lacrimal sac with iodized oil, x-ray examination showed stricture of the duct in the middle meatus of the nose. The epiphora was relieved by a dacryocystostomy done above the stricture.

Plasma Transfusion

P. Brodin and F. Saint Girons, before the Société médicale des Hôpitaux de Paris, stressed the advantage of using not the whole blood but only the plasma in severe hemorrhages. According to their view the danger of hemorrhage lies less in the loss of the erythrocytes than in the loss of the volume of blood. When this is reduced to one fourth, death is inevitable. In war times it may not be possible to use only living blood and recourse to stored blood may be necessary. This involves dangers. R. Benda, at the same meeting, reported the history of a woman aged 52 who had undergone five transfusions of fresh blood within six months in large doses and who died six hours after slow injection of 100 cc. of stored blood of group O taken sixteen days previously. This indicates that stored blood may become toxic and cause fatal hemolysis after a certain time, varying according to the particular case. To avoid these accidents, the origin of which is probably determined by the type of the blood, only the plasma is kept, after centrifugation and separation from the red corpuscles. The plasma can be stored for weeks and months. Unlike the serum, the plasma is not toxic, even if applied to different blood groups. Professor Pittaluga, of Madrid, before the Société de chirurgie, expatiated on the lessons learned regarding blood transfusion during the three years of civil war in Spain. Whether intended for immediate use or for conservation, the blood was subjected to the customary tests including the test for malaria. The blood of universal donors never caused accidents. It is important, he said, to store the blood at a constant temperature of 37.4 F., which required special equipment. Under these conditions its usefulness could be extended to two weeks. Reheated at 100.4 F.

and slowly injected, shocks rarely resulted from the transfusion. Neumann, of Brussels, added confirmation to these observations from his extensive experience.

Effect of Radium on the Tubercle Bacillus

In one of the last sessions of the Académie des sciences, P. Bonet-Maury and H. R. Olivier discussed the effects of the use of radium on the behavior of tubercle bacilli. Their method consists in dissolving the total radiation of the radon in a microbial suspension. With powerful doses the respiration of the irradiated bacillus continues, though reduced to about one sixth, for several days. The bacilli are in a state of "postponed death," still alive but no longer virulent. Owing to the destruction of bacillary virulence while keeping the bacilli alive, the authors were able to bring about the immunization of guinea pigs. In man they obtained encouraging therapeutic results with safety. This "radium vaccine" engenders hopes of interesting developments in the immunization against tuberculosis and in its treatment.

The Closing of Some Dental Laboratories

The minister of public health has ordered the closing of 123 dental laboratories which were conducted by dental technicians in violation of the law. In 1923 dental technicians obtained permission to practice. However, the law issued by former Minister Saveanu deprived some of them of practice on the ground that they obtained their permission illegally. The dental technicians attacked the law on the ground that it violated their rights, but the supreme court upheld the law. Thereupon a long controversy arose between dental surgeons and dental technicians. The litigation came to an end by the issue of the Moldovan law in 1930. This law favored some dental technicians in that those who in 1930 had been in practice for fifteen years, could take a one year theoretical and practical course and then be examined for license to practice. Those who had practiced fifteen years and already were 42 or more years of age were absolved from attending the course and needed only to pass the examination. As 123 dental technicians did not fulfil this requirement, the minister of health ordered their laboratories to be closed.

Committees Appointed by the Ministry of Health

The government some time ago empowered the Ministry of Health to appoint technical committees to study public health problems and to make proposals regarding most urgent matters needing attention. In all, nineteen committees have been appointed to study typhus fever, malaria, eugenics, maternity and child welfare, insurance against tuberculosis, cancer, venereal diseases, rheumatism, malnutrition and deficiency diseases, and dentistry with especial attention to the function of dental technicians. Committees are also being appointed to stimulate the campaign against alcoholism and trachoma, to promote the standardization of biologic products and to investigate means of fostering international relations in health matters.

Professor Daniel Honored

The Faculty of Medicine of the University of Bordeaux celebrated the conferring on Constantin Daniel, professor of obstetrics and gynecology at the Buearest University, of the degree of doctor honoris causa. The diploma and the insignia were handed to him in the presence of the deans of all the faculties of Bordeaux University and notables of the city of Bordeaux. Prof. Gabriel Boussagol, rector of the Bordeaux Academy, and Prof. Josef Guyot eulogized the Rumanian savant. Thereupon Prof. Constantin Daniel read an elaborate paper on the influence of French medical sciences on the Rumanian universities.

BERLIN

(From Our Regular Correspondent)

Nov. 1, 1939.

Homeopathy and Lay Practitioners

The Deutscher Centralverein homöopathischer Aerzte recently commemorated its hundredth session. Among the speakers was Prof. Paul Martini, clinician in Bonn, who is known for his thorough critical reexaminations of the therapeutic value of substances designated as medicaments. Retests were necessary, he said, because homeopathy had been vindicated of late years in a number of cases at the hands of the national socialist party, converting some physicians from an attitude of rejection to one of uncritical assent. Plans are being made by the public health department of the reich to conduct an extensive examination of all homeopathic curative procedures.

Recently a meeting also took place of the movement for German public health in Stuttgart. This body represents the so-called lay practitioners (heilpraktiker). Their status in the reich was recently regulated by law (THE JOURNAL, June 10, p. 2449). The presiding officer made several peculiar statements; e. g., that the union between medicine taught in schools and lay medical practice was now completed, the former in future taking over the experiences of lay practitioners; that lay practitioners rejected occult methods as employed in healing by prayer and in remote treatment in accordance with specimens of writing, but not magnetic therapy. Besides they adhered, he said, to ocular diagnosis in spite of medical objections. The 5,000 legalized lay practitioners in Germany are determined to be distinguished from the quacks.

The law regarding lay practitioners also affects all persons who treat speech defects with or without psychic methods, those who professionally occupy themselves with psychotherapy and the psychology of healing, with curative gymnastics and with respiratory cures; likewise professional teachers of vision (seh-lehrer), proprietors of schools of vision (seh-schulen) and those who treat fractures (exclusive of purely orthopedic measures) and those who profess to cure leg and foot troubles (exclusive of pedicures).

Significant for the social alinement of lay practitioners, who come from the lower strata of society, was the announcement of one of the highest medical functionaries of national socialism, Dr. Blome, at last year's congress for internal medicine that it was planned to admit lay practitioners to the sick funds. Whether this was feasible was another question, since lay practitioners might not desire it on account of the low compensations granted by the sick funds. Moreover, he and the medical leadership of the party in power would welcome their admission. In this way, he said, it would not always be the sick fund physician on whose back professional questions are fought out; for, in addition to his low fees, many patients hold him responsible for alleged inferior services provided by the sick funds and for many other things. This frank avowal is quite significant for the attitude of those insured toward the sick fund system in Germany. Dr. Blome is the representative of the state medical leader for medical continuation training. In the meantime, lay practitioners have signified their willingness to participate in sick fund insurance with the declaration, however, that they did not surrender their conviction that their services would before long receive a more just compensation. This implies that they expect better fees than the physicians. Privately managed sick funds, which compensate on a higher scale than those of the state, have already admitted lay practitioners. In the Rudolf Hess Hospital in Dresden an "academy for new German medicine" is to be established. Hess, who is close to Hitler, is the great promoter of all unscientific paramedical movements.

AUSTRALIA

(From Our Regular Correspondent)

Oct. 25, 1939.

Community Plan for Medical Services

Contract practice as a private enterprise has now been commenced in Australia. Medical services at Canberra (the federal capital city of Australia) have been reorganized by the introduction of a community plan on a voluntary basis. Five of the doctors who reside in the capital are conducting the scheme, which is open to all residents earning up to £520 a year and their dependents. Contributions are planned on a sliding scale, with a maximum of £3-3-0 a year for persons with an annual income of £520 and £6-6-0 for these people with their dependents. Liberal benefits are to include unlimited medical benefits during illness, a complete medical overhaul every year, a full service for obstetric cases, assistance when necessary at operations, and medical attendance at doctors' offices or in the homes of contributors between the hours of 8 a. m. and 8 p. m. on week days and until 1 p. m. on Saturdays. Disabilities due to misconduct and injuries or sickness already provided for by insurance are not covered by the scheme. Additional fees may be charged for traveling beyond a 4 mile limit and for urgent attention outside specified hours. The British Medical Association in Australia is following the experiment closely. The city already has a government-controlled compulsory hospital benefit scheme.

War Time Measures in Australia

The spread of war in Europe and the potential danger of war in this country have been responsible for greatly increased activity in air raid precaution work and in other schemes for the protection of civilians in times of emergency. Government and voluntary organizations have instituted instruction classes both for officials and for civilians, and plans for the evacuation of each of the larger cities are well in hand. Extensive plans have also been made for the organization of an emergency blood transfusion service. These include provision for the storage of blood if necessary and the grouping, testing and listing of a large number of donors from both the military and the civilian ranks. Special attention is being given to the feeding of the military forces in Queensland. An increased supply of salad vegetables, fruit, eggs and milk, the substitution of whole meal for white bread, and milk and fruit bars in the canteens are new departures at present under consideration. Consideration has also been given to the emergency organization of the medical profession with due regard to both military and civil needs. Special lectures have been arranged for numbers of the profession on war time medicine and surgery.

Birth Rate Recovery by Australia

While many countries at present are faced with the national problem inherent in a net reproduction rate of less than 1, recent statistics reveal that births in Queensland are well above the level required to fill the places of the present generation. Figures for the whole of Australia show that there has been a recovery practically to the displacement level. A separate calculation for Queensland was first made on the 1938 birth registrations and gave the result of 1.09. A calculation for South Australia gave the low figure of 0.85. The latter may be associated with the fact that 54 per cent of the population of that state lives in the metropolitan area. The latest figure for Australia (1937) is 0.99. Comparisons with the net reproduction rates of other countries give Japan (1930) 1.57, Canada (1931) 1.32, Italy (1937) 1.13, the Netherlands (1937) 1.12, Queensland (1938) 1.09, New Zealand (1938) 1.02, Australia (1937) 0.99, the United States (1935 white population) 0.96, Denmark (1937) 0.95, Germany (1936) 0.93, France (1937) 0.87, Great Britain (1937) 0.80, Sweden (1936) 0.76.

Nutrition in New Zealand

New Zealand has the reputation of being a country that produces a healthy and virile people. Recent inquiries have tended to throw some doubt on this generalization. The "protective foods" are still fairly expensive and as a consequence New Zealanders tend to consume meat as their main first class protein and to bulk their diet with white bread, cakes, cane sugar and tea. New Zealanders are the largest meat eaters in the world (about 250 pounds a head annually). This statement is amply borne out by a survey of food consumption for the last few years. Total food consumption divided by total population shows that each person consumes daily from 6 to 7 ounces of sugar, approximately 1 pound of red meat, a half pound of white flour, two thirds of a pint of milk, two thirds of an egg, one-third ounce of cheese and from 2 to 3 ounces of butter (not margarine). Most of the milk is taken by adults in tea and the egg in cakes.

The available evidence suggests that about 97 per cent of the school children show signs of dental caries and that more than 50 per cent of the adults have false teeth. It is also reported that one in every twenty persons in the country is in the hospital every year, chiefly for such complaints as appendicitis, tonsils and goiter. The adult population also suffers to no inconsiderable degree from digestive complaints, rheumatism and neuritis.

It is interesting to note at what age the breakdown in the health of the children begins to occur. Up to the age of 8 or 10 months most of the children seem to be in good condition. After that age it is customary to cut down the amount of milk, cod liver oil and orange juice, with the result that the calories are obtained mainly from refined starches and the resistance of the child tends to decrease. By the time the children are going to school, dental decay has become common. But for the past two years an additional half pint of milk has been supplied daily in the schools, and this is having a beneficial effect.

Another factor which has an influence on the nutrition of New Zealand is the quantity of cakes and pastry that are consumed. No morning, afternoon or evening gathering is complete without an array of these delicacies, and with the great majority of the population (largely female) they constitute the mainstay of the day. The tea drinking habits are the surprise of every visitor; strong tea, often plentifully sugared, accompanies every meal, even dinner.

Summing up the nutritional problems of New Zealand, it is suggested that (1) calories are adequate, (2) first class protein is adequate but ill chosen, and (3) vitamins B₁ and D are sub-optimal, as are iron, calcium and iodine. This situation is brought about by a combination of poor knowledge of nutritional science and of the relatively high price of many of the protective foodstuffs. Home science has always been a feature of the University of Otago, and extension activities are in operation. Nutrition education has been furthered by the Women's Food Value League, on the executive committee of which are British Medical Association members. There are scattered foci of reform such as the Auckland Boy's Grammar School the results of which have been stimulating.

Marriages

ELSIE G. WESTLEY, San Antonio, Texas, to Capt. E. F. Adams of Fort Sam Houston, September 2.

OSCAR MILTON MARCHMAN JR., Dallas, Texas, to Miss Mary Alice Yates of Longview, September 7.

WARREN D. HANSEN to Miss May Wintlers, both of Wisner, Neb., August 25.

WOODROW W. SCHMELA to Miss Dora Larson, both of Omaha, September 3.

Deaths

Martha Wollstein, Grand Rapids, Mich.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1889; at one time demonstrator in histology and demonstrator in pathology at her alma mater; formerly assistant clinical professor of diseases of children and pathology, Columbia University College of Physicians and Surgeons, New York; member of the American Pediatric Society; associate of the Rockefeller Institute for Medical Research from 1906 to 1921; for many years on the staff of the Babies Hospital, New York; aged 70; died, September 30, in the Mount Sinai Hospital, New York.

Allan Joseph Hruby ☉ Chicago; University of Illinois College of Medicine, Chicago, 1913; fellow of the American College of Physicians; school health officer, 1916-1917; dispensary physician to the Chicago Municipal Tuberculosis Sanitarium, 1917-1918, superintendent, 1918-1923, and secretary and member of the board of directors since 1931; aged 49; at various times on the staffs of Cook County Hospital, St. Anthony's Hospital and the Washington Boulevard Hospital, where he died, November 18, of lobar pneumonia.

Herbert Preston Leopold, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1896; clinical professor of surgery at his alma mater; fellow of the American College of Surgeons; surgeon to the Homeopathic State Hospital, Allentown; consulting surgeon to the Coatesville (Pa.) Hospital, West Jersey Homeopathic Hospital, Camden, and the Homeopathic Hospital, Wilmington, Del.; aged 65; died, September 21, at his summer home in Tannersville, Pa., of acute coronary thrombosis.

Milford Levy ☉ Baltimore; College of Physicians and Surgeons, Baltimore, 1915; member of the American Psychiatric Association; assistant professor of neurology at the University of Maryland School of Medicine and College of Physicians and Surgeons; served during the World War; on the staffs of the Mercy, University, South Baltimore General, Sinai, Bon Secours and St. Agnes' hospitals; aged 47; died, October 10, in Pikesville, Md., of rheumatic cardiovascular disease and aortic stenosis.

Michael Matthew Jordan ☉ Worcester, Mass.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1905; member of the American Psychiatric Association and the New England Society of Psychiatry; served during the World War; aged 55; on the staffs of St. Vincent's Hospital and the City Hospital, where he died, September 30, of coronary thrombosis.

Harry Roland Lickle ☉ Baltimore; Maryland Medical College, Baltimore, 1909; assistant in medicine from 1920 to 1923 and instructor in medicine 1923-1924, University of Maryland School of Medicine; on the visiting staffs of the University, Mercy, St. Agnes', Maryland General, Women's and the West Baltimore General hospitals; aged 50; died, September 13, of cerebral hemorrhage.

Oran Idnre Cutler ☉ Loma Linda, Calif.; College of Medical Evangelists, Loma Linda, 1924; professor of pathology and bacteriology at his alma mater; member of the American Society of Clinical Pathologists; on the staffs of the Los Angeles General Hospital, Riverside County Hospital, Arlington, and San Bernardino (Calif.) County Hospital; aged 39; died, September 15.

Frank M. Register, Kinston, N. C.; Kentucky School of Medicine, Louisville, 1893; member of the Medical Society of the State of North Carolina; for many years connected with the state board of health; formerly health officer of Wayne County; medical superintendent of the Caswell Training School; aged 69; died, September 28, of intestinal obstruction and chronic myocarditis.

Edward McCarty Armstrong ☉ Houston, Texas; University of Virginia Department of Medicine, Charlottesville, 1892; fellow of the American College of Surgeons; member of the visiting staff of St. Joseph's Infirmary and Methodist Hospital; surgeon to the Memorial Hospital; consulting surgeon to the Jefferson Davis Hospital; aged 68; died, October 7.

Charles Tilden Howard, Hingham, Mass.; Boston University School of Medicine, 1898; professor emeritus of surgery at his alma mater; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; consulting surgeon to the Massachusetts Memorial Hospitals; aged 67; died, September 6.

Winfield Harrison Ammarell ☉ Birdsboro, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1909; past president of the Berks County Medical Society; at one time county coroner; president of the board of health and member of the school board; aged 56; died, September 1, of Hodgkin's disease.

Albert Ridgeley, Washington, D. C.; Howard University College of Medicine, Washington, 1900; associate professor emeritus of anatomy at his alma mater; for many years health inspector in the public schools; served during the World War; aged 63; died in September at the Veterans Administration Facility.

Albert Edwin Leach, Mount Morris, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1891; member of the Medical Society of the State of New York; health officer; aged 73; died, September 8, in the Wyoming County Community Hospital, Warsaw, of coronary thrombosis.

Fred Allen Fuller, Jacksonville, Texas; University of the South Medical Department, Sewanee, Tenn., 1908; member of the State Medical Association of Texas; aged 55; on the staff of the Nan Travis Memorial Hospital, where he died, October 7, of chronic hypertension and nephritis.

George Holt Barksdale ☉ Charleston, W. Va.; Northwestern University Medical School, Chicago, 1908; served during the World War; fellow of the American College of Physicians; on the staffs of the Charleston General and St. Francis hospitals; aged 57; died, October 8.

Lorenzo W. Swope ☉ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1896; fellow of the American College of Surgeons; for many years on the staff of the Western Pennsylvania Hospital; aged 76; died, September 14, of cerebral hemorrhage and arteriosclerosis.

Winfred Wylie ☉ Phoenix, Ariz.; Rush Medical College, Chicago, 1877; Long Island College Hospital, Brooklyn, 1878; fellow of the American College of Surgeons; past president of the Arizona State Medical Association; also a lawyer; aged 84; died, September 23, in Glendale, Calif.

Louis Augustus Fuerstenau, Milwaukee; Northwestern University Medical School, Chicago, 1909; president of the Milwaukee Society of Clinical Surgery; aged 58; on the staff of St. Mary's Hospital, where he died, September 21, of benign tumor of the pyloric end of the stomach.

George Washington Cassady, Chicago; Jenner Medical College, Chicago, 1900; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; aged 72; on the staff of St. Elizabeth's Hospital, where he died, October 10, of pernicious anemia.

Lot Richard Henry, North Middletown, Ky.; Kentucky University Medical Department, 1902; member of the Kentucky State Medical Association; formerly mayor and member of the school board; aged 65; died, October 9, of coronary occlusion, mitral stenosis and hypertension.

William Stephen Beck, Indianapolis; Medical College of Indiana, Indianapolis, 1888; member of the Indiana State Medical Association; formerly a lawyer; at one time county coroner and secretary of the county board of health; aged 76; died, October 6, of heart disease.

Mary Angela Spink, Indianapolis; Medical College of Indiana, Indianapolis, 1887; member of the Indiana State Medical Association; president and medical director of the Dr. W. B. Fletcher's Sanatorium; aged 75; died, September 3, in Lisbon, N. H., of heart disease.

Robert Swift Patten, Danville, Pa.; Jefferson Medical College of Philadelphia, 1901; member of the Medical Society of the State of Pennsylvania; for many years physician for the public schools; aged 65; was found dead in bed, September 26, of coronary thrombosis.

John Macaulay Gunning, Spokane, Wash.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; aged 72; died, October 7, at the Deaconess Hospital of chronic myocarditis, mitral regurgitation and cholangitis.

Sarah Louise Weintraub, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1883; member of the Medical Society of the State of Pennsylvania; formerly a medical missionary in Syria; aged 78; died, September 11, in Avalon, N. J.

Joseph Lawrence Morrissey, Elmhurst, N. Y.; Long Island College Hospital, Brooklyn, 1916; served during the World War; aged 48; on the staff of the Flushing (N. Y.) Hospital, where he died, September 12, of acute pancreatitis.

Lawson Walter McKenzie, Washington, D. C.; Medical College of Indiana, Indianapolis, 1904; formerly physician in the insurance service of the Veterans Administration; aged 61; died, September 20, of coronary occlusion and arteriosclerosis.

George R. Herkimer, Dowagiac, Mich.; Hahnemann Medical College and Hospital, Chicago, 1890; served during the World War; at various times member of the school board, and mayor; aged 73; died, October 1, of cerebral embolus.

Irving C. Wood, Omaha; Jefferson Medical College of Philadelphia, 1880; at one time mayor of Logan, Iowa; aged 82; died, September 7, in the Nebraska Methodist Episcopal Hospital and Deaconess Home of myasthenia gravis.

John Jacob Fossler, Millard, Neb.; University of Nebraska College of Medicine, Omaha, 1907; for many years a member of the school board; aged 62; died, September 27, in the Immanuel Hospital, Omaha, of myasthenia gravis.

Loring Watson Turrell, Smithtown Branch, N. Y.; Yale University School of Medicine, New Haven, Conn., 1936; member of the Medical Society of the State of New York; aged 30; died, September 8, of idiopathic pneumothorax.

William Dana Pursel @ Phillipsburg, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; aged 64; died, September 18, in the Easton (Pa.) Hospital of an overdose of morphine, self administered.

John Franklin Calbreath, Portland, Ore.; University of California Medical Department, San Francisco, 1875; member of the Oregon State Medical Society; aged 85; died, October 4, of hemorrhage from an esophageal varix.

Kenneth Israel Hoffman @ New York; Cornell University Medical College, New York, 1921; on the staff of the New York Polyclinic Medical School and Hospital; aged 42; died, October 10, in a local hospital.

George Yerkes Woodland, Philadelphia; Medico-Chirurgical College of Philadelphia, 1895; for many years a medical inspector in the public schools; served during the World War; aged 72; died, September 10.

William S. Higbee, Philadelphia; Jefferson Medical College of Philadelphia, 1883; member of the Medical Society of the State of Pennsylvania; aged 77; died, September 12, in the Methodist Hospital.

Owa O. Hausch, Painesville, Ohio; Cleveland Medical College, 1891; member of the Ohio State Medical Association; for many years county coroner; aged 74; died, October 14, of coronary thrombosis.

Clifford Mitchell, Chicago; Chicago Homoeopathic Medical College, 1878; formerly professor of renal diseases and clinical urology at the Hahnemann Medical College and Hospital; aged 85; died, October 19.

Earl Edgar Miller, Culbertson, Neb.; University of Nebraska College of Medicine, Omaha, 1924; aged 40; died, September 21, in St. Catherine's Hospital, McCook, of increased intracranial pressure.

Benjamin Garleat Benson, Webster Groves, Mo.; St. Louis College of Physicians and Surgeons, 1888; served during the World War; aged 72; died, October 8, of coronary occlusion and arteriosclerosis.

Welland A. Peck, Scranton, Pa.; Medico-Chirurgical College of Philadelphia, 1899; member of the Medical Society of the State of Pennsylvania; aged 70; died, September 20, of acute endocarditis.

Albert Warren Stearns Jr., Billerica, Mass.; Tufts College Medical School, Boston, 1939; aged 25; died, September 5, in the Huntington Memorial Hospital, Boston, of Ewing's sarcoma of the left ileum.

Amelia Weicksel, Perkasic, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1904; aged 78; died, September 1, in the Grand View Hospital, Sellersville, of cerebral thrombosis and myocarditis.

William Henry Christian, Pittsburgh; Leonard Medical School, Raligh, N. C., 1905; member of the Medical Society of the State of Pennsylvania; aged 61; died September 23, of aortic stenosis.

Joseph B. Cowen, Hamilton, Ohio; Medical College of Ohio, Cincinnati, 1897; aged 63; on the staffs of the Fort Hamilton Hospital and Mercy Hospital, where he died, October 2.

William M. Wilson @ Weaverville, Calif.; College of Medical Evangelists, Los Angeles, 1931; aged 40; died, September 10, of chronic nephritis, hypertension and cerebral hemorrhage.

Guy Ross Caley, Princeton, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; aged 63; died, September 26, of heart disease and chronic nephritis.

John William Adams, Waterville, Wash.; Jefferson Medical College of Philadelphia, 1887; formerly county health officer; aged 78; died, October 10, in a hospital at Wenatchee.

William Lamar Law, Prattville, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1894; aged 68; died, October 13, in a hospital at Atlanta, Ga., of myocarditis.

John William Greer, Franklin, Tenn.; Memphis Hospital Medical College, 1899; member of the Tennessee State Medical Association; aged 69; died, October 16, of coronary thrombosis.

Ira A. Griffin, Snyder, Texas; Memphis (Tenn.) Hospital Medical College, 1908; member of the State Medical Association of Texas; aged 55; died, October 2, of cirrhosis of the liver.

Charles A. Haefner, Youngstown, Ohio; Central College of Physicians and Surgeons, Indianapolis, 1905; aged 64; died, October 10, in St. Elizabeth's Hospital of diabetes mellitus.

William D. Wilkinson, Boston; Middlesex College of Medicine and Surgery, Waltham, Mass., 1928; aged 40; was found dead, September 23, of a self-inflicted bullet wound.

Frederick Rutherford Warnock, Pembroke, Mass.; Columbia University College of Physicians and Surgeons, New York, 1937; aged 28; died, September 12, of appendicitis.

Carlyle Junius Edwards, Raleigh, N. C.; Medical College of Virginia, Richmond, 1917; member of the Medical Society of the State of North Carolina; aged 50; died, September 30.

Edwin Justus Haster, Dardanelle, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1924; member of the Arkansas Medical Society; aged 39; died, September 24.

Charles Gowen Buchanan Klophe, Ontario, Calif.; College of Physicians and Surgeons of Chicago, 1887; aged 72; died, September 17, of heart disease and arteriosclerosis.

William E. Jenkins, Charleston, Miss.; Louisville (Ky.) Medical College, 1887; at one time mayor of Eupora; formerly county health officer; aged 73; died, September 28.

Daniel E. Richards, San Diego, Calif.; Western Pennsylvania Medical College, Pittsburgh, 1894; aged 81; died, September 4, of arteriosclerosis and coronary occlusion.

Mark Johnson Williams, Oxford, Ala.; Birmingham Medical College, 1902; member of the Medical Association of the State of Alabama; aged 61; died, September 23.

Eugene Wolcott Whitney, La Mesa, Calif.; Rush Medical College, Chicago, 1878; past president of the Utah State Medical Association; aged 85; died, September 26.

Edward Gardner De Wolf, Somerville, Mass.; Dartmouth Medical School, Hanover, N. H., 1893; aged 70; died, September 29, in Worcester of bronchopneumonia.

John Albert Wilson @ New York; Columbia University College of Physicians and Surgeons, New York, 1917; aged 52; died, September 5, in Nantucket, Mass.

Harold Kirby, Minneapolis; University of the City of New York Medical Department, 1891; aged 71; died, September 23, in Louis Park, Minn., of sarcoma.

Rasmus Hansen Madsen, Palo Alto, Calif.; University of California Medical Department, San Francisco, 1901; died, September 22, in the Palo Alto Hospital.

Harvey Jason Hassard, Portage la Prairie, Man., Canada; Trinity Medical College, Toronto, Ont., 1901; aged 61; died, September 29, of coronary occlusion.

Willis J. Evans, Denver; Long Island College Hospital, Brooklyn, 1905; veteran of the Spanish-American War; aged 65; died, October 3, of myocarditis.

James Edward Childs, San Diego, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; aged 78; died, September 5.

Frank L. Harold, Richmond Ind.; Physio-Medical College of Indiana, Indianapolis, 1903; aged 60; died, October 14, of acute nephritis and enterocolitis.

Daniel Alfred Stubbs, Oxford, Pa.; Jefferson Medical College of Philadelphia, 1874; aged 87; died, September 25, in West Chester of pneumonia.

Frank Dudley McCulloch, Moose Jaw, Sask., Canada; McGill University Faculty of Medicine, Montreal, Que., 1925; aged 40; died, September 8.

Ernest Maxwell Fine, Crescent City, Calif.; Cooper Medical College, San Francisco, 1898; aged 66; died, September 30, of cerebral hemorrhage.

A. E. G. HALL Alfred Ernest George Hall Again Reenters the United States and Becomes "Acquainted" with Another Better Business Bureau

A. E. G. Hall has twice previously been discussed in the columns of the Bureau of Investigation in THE JOURNAL. Both his penitentiary pictures and his fingerprints have been reproduced in our pages. The article which appeared in the issue of Oct. 13, 1928, called attention to the fact that Hall had encountered difficulty with the Rochester (N. Y.) Better Business Bureau and, after a heart-to-heart talk with Mr. F. M. Willson, the manager, canceled his remaining lectures and left the city.

The *Spotlight*, a publication of the Better Business Bureau of San Francisco, carried in its September 1939 issue a story under the heading "Dr. Alfred G. Hall, Famous Swindler, Nabbed in Marin County." This item reads as follows:

"Dr. Alfred G. Hall, international swindler, pseudo-religious lecturer and promoter of the World Fellowship of Faith and Service, was apprehended in San Rafael on August 19 by Police Chief John B. Ruschetti, charged with illegal entry into the United States. The Better Business Bureau's tip to immigration authorities caused Hall's arrest. 'Plans for a \$100,000 university to be erected in Marin County were under way at the time Hall was nabbed. One follower presented the organization with a fifteen-acre site for the university. Others were urged to contribute finances for the enterprise. Hall officiated at a dedication ceremony a short time ago. Chief Ruschetti became suspicious when he observed Hall living with his followers in tents on the proposed site for the university.'

"Inquiries from persons who listened to 'Dr.' Hall's lectures at Western Women's Club, San Francisco, caused the Better Business Bureau to check his antecedents. It developed that he has a long record of promotions. At one time he was a self-appointed prison chaplain, but a few weeks later was lodged in the same jail where he had urged others to 'follow the straight and narrow path.'

"An eventful career, marked by numerous arrests, was indicated by reports received from Better Business Bureaus throughout the United States and Canada. While he uses the title of 'Dr.', it has not been substantiated that he has such a degree. In discourses on 'Sex and Civilization', he claimed to be a specialist from London, Paris, Geneva and Vienna. In Toronto, a newspaper described his sex lectures as 'utterly filthy and unscientific discourses on sexual subjects.'

"At Richmond, Indiana, he created the 'American Academy of Psychological Research', modestly styled himself the 'Dean', and distributed degrees lavishly, the Bureau learned. In 1926, he created an organization to lecture against the use of narcotics, voting himself a satisfactory salary for his lectures. In Chicago, he operated a confidence game which brought him a sentence of six months in the House of Correction.

"One of Hall's lectures in San Francisco was on the subject of 'Wandering or Going Straight.' Evidently he preferred, in his personal matters, to wander."

For purposes of reference, Hall's record, as far as the Bureau of Investigation had it at the time of an article published in THE JOURNAL, May 18, 1935, was as follows:

- 1923—Vancouver; arrested for obtaining credit under false pretenses. Sentence suspended.
- 1924—Vancouver; arrested for conspiring to defraud. Case dismissed. Again arrested, charged with obtaining money under false pretenses and sentenced to six months at hard labor in Oakalla Prison.
- 1925—Vancouver; arrested for obtaining money under false pretenses. Sentenced to twelve days. Again arrested for obtaining money under false pretenses and sent to jail.
- 1926—Chicago; arrested on charge of operating a confidence game and obtaining money under false pretenses. Was fined and sentenced to six months in the House of Correction.
- 1927—Chicago; arrested for practicing medicine without a license. Charge nolle prossed for lack of prosecution. At the same time Hall was taken into custody by the United States authorities as an alien who had violated the Immigration Act. He was given hearing and deported.
- 1928—Toronto; arrested on the charge of vagrancy. Charge withdrawn, as he had money in his pocket.
- 1930—Toronto; arrested for swindling the Royal York Hotel of about \$1,100. Sentenced to six months in the Ontario Reformatory.
- 1932—Cleveland; arrested by the police department and again deported to Canada.
- 1933—Toronto; arrested and found guilty of theft. Sentenced to two years in the Kingston Penitentiary.

The 1935 article detailed his escapade in Toronto in 1930, in which he ran a bill of \$220 at the King Edward Hotel

and, according to the Toronto papers, Hall persuaded the Royal York Hotel to put on a \$1,000 banquet in connection with which he was later charged with obtaining credit by false pretenses. He had introduced himself as a doctor and general organizer of the National Order of Canada, which he claimed was paying him \$12,000 a year and expenses. As a matter of fact, the Order had seventy-five members at that time, but Hall was not receiving any salary from it. He was convicted and sentenced to six months determinate and six months indeterminate in the Ontario Reformatory in May 1930. Said THE JOURNAL in 1935:

"Not content with this sample of Ontario justice, Hall in 1933 was put on trial in Toronto on a charge of theft. Hall and one Fred Hastings, with whom he was associated, were alleged to have stolen \$2,482 paid to them as subscriptions for various magazines and periodicals while they operated an organization known as the Dominion Publications Bureau. Hall acted as his own attorney, and in addressing the jury he said: 'You have not before you the ordinary type of criminal that goes out to plunder and steal.' He pleaded 'justification and honest error.' Hall told the jury, also, that he had written books about criminals, had looked after them spiritually, had studied them psychologically, and their actions were not the same as his own. He again charged that he was being hounded by the authorities. Hall was very persuasive and dragged the usual red-herrings across the trail, and the judge, in charging the jury, warned them not to allow themselves to be carried away by frenzied eloquence.' They did not. Hall was sentenced to two years in the Kingston Penitentiary.

"A few weeks ago Hall completed his two-year sentence in the penitentiary. Apparently no sooner was he out of the penitentiary than he hired a hall, in accordance with his usual methods, and, as the Toronto *Evening Telegram* reported, 'smartly dressed in striped trousers, black coat, wing collar and flowing tie', addressed an audience of less than a hundred—telling them what an unpleasant place the Kingston Penitentiary is. He also made charges against the warden of the penitentiary and the Hon. D. M. Ormond, Superintendent of Penitentiaries at Ottawa. Hall is reported to have stated to his audience that he didn't regret his experience in the penitentiary and that since getting out he had written a 100-page report. He claims to have been one of those sentenced to be paddled while he was in the penitentiary, but it appears from the report that, unfortunately for the public—and possibly for Hall himself—the sentence was not carried out."

This article concluded as follows: "The reason for calling attention to A. E. G. Hall is that this quack and ex-convict is more than likely to make another attempt to get into the United States. If he does, it can be taken for granted from his past record that he will live by his wits and at the expense of the American public."

Sooner or later Hall may catch on to the idea that he is not wanted in this country. Various protective organizations are doing their utmost to prevent his nefarious activities. Past experience, however, leads to the belief that he will spend the rest of his life playing true to form the role of psychological quack that he has selected for himself.

MISBRANDED "PATENT MEDICINES" Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Correcol.—Modern Health Products, Inc., Milwaukee. Composition: Essentially Lallemandia royleana (a mucilaginous substance) and a smaller amount of karaya gum. Fraudulently represented to be a health product and to correct colonic disorders.—[N. J. 29765; March 1939.]

Life (Miracle) Mineral Water.—Rocky Mountain Mineral Co., and George A. Manning (agent), Bessemer, Ala. Composition: Chiefly iron sulfate with small amounts of other mineral substances, not named. Fraudulently represented as a remedy for stomach troubles, arthritis, old sores, female complaints, blood diseases, etc.—[N. J. 29753; March 1939.]

Slim.—Modern Health Products, Inc., Milwaukee. Composition: Essentially senna (70 per cent), orange peel, anise, bladderwrack, buckthorn bark, dried apple, and centaury flowers. Fraudulently represented to normalize overweight, make the body slim and act as a health product.—[N. J. 29765; March 1939.]

Correspondence

THE PSYCHOLOGY OF THE BIRTH CONTROL CONTROVERSY

To the Editor:—In THE JOURNAL October 21 appears an article by Dr. George Kosmak with regard to birth control.

Dr. Kosmak refers to the "hysteria" of some one or other connected with the birth control movement; he refers to an "insane" approach and the "agitation" of many people. He refers to "loose thinking" and again to their "hysteria," to their "viciousness" and to their "inadequate reasoning."

Dr. Kosmak uses these psychiatric designations as if to contrast his own mental poise with the mental ill health of those with whom he doesn't agree. I am well acquainted with the persons who are chiefly responsible for having brought the problem of birth control to the more serious attention of our profession and of the public generally, and in my capacity as a psychiatrist I must offer the opinion that no signs of hysteria, insanity, viciousness or agitation have made their appearance. On the contrary, I should say that far more quiet, intelligent reflection and far less emotion have been manifested by them than by Dr. Kosmak in his somewhat excited diatribe against them.

Dr. Kosmak is entirely correct in saying that the question deserves scientific study, and this is precisely what the non-professional advocates of birth control have sought. There is nothing to prevent Dr. Kosmak's doing this without denouncing those earnest and honest individuals, all of them friends of the medical profession, who have brought this problem out of the realm of prudish and bigoted suppression to the point where the scientific intelligence of Dr. Kosmak and others can be applied to its solution.

KARL MENNINGER, M.D., Topeka, Kan.

[Dr. Menninger's letter was submitted to Dr. Kosmak, who replied as follows:]

To the Editor:—I had fully expected reactions to my paper such as those enunciated by Dr. Menninger. Notwithstanding his doubts about my designation of certain groups of "birth control" enthusiasts as hysterical and given to exaggeration and loose thinking, I feel that my judgment of their activities will be generally endorsed by many fair minded members of the profession as well as by laymen who can trace the connection between their propaganda and the widespread results of the desire for avoiding pregnancy under all circumstances. In this connection one might also refer to the disgusting commercial exploitation of contraceptive devices which is encountered on every hand and which may be regarded as a response to the public dissemination of the literature and utterances of propagandist groups. One cannot question the sincerity of the rational advocates of birth control for medical and, perhaps, limited social indications, but my particular condemnation applies to the more radical groups who have fathered the extensive newspaper, magazine and other publicity with which a perfectly legitimate movement has been surrounded and which has worked to its detriment. The terms which I employed in my paper to designate those activities would be applicable in common parlance, although they may not agree with the more scientific (?) diagnostic designations of the psychiatrist. In view of the many commendatory letters received, my views evidently met the approval of those less hampered by such academic distinctions.

As for any expressions of friendliness toward the medical profession from certain advocates of the unrestrained dissemina-

tion of birth control information as claimed by Dr. Menninger, this has been developed, in my opinion, largely as a matter of expediency only in more recent years.

A careful reading of my paper would have disclosed to Dr. Menninger that I made no accusations whatever against those earnest and sincere persons who have approached the problem as a health or social measure in a purely professional sense. But these are not the people to whom I refer, and one need not seek very far to learn the identity of the others.

Physicians as a class must be accused of indifference and laxity in their attitude toward the important questions involved in the subject of what is popularly but erroneously designated as "birth control." If they can be stimulated to assume their responsibilities in the matter, this would prove a satisfactory ending to the discussion and constitute a sufficient reason for the attention which my own small effort may have generated.

GEORGE W. KOSMAK, M.D., New York.

REDUCTION OF MOTOR ACCIDENTS

To the Editor:—The most serious medical problem in the United States today is the motor accident. A special committee should study this problem from all angles, such as (1) road construction, (2) proper universal marking of roads, (3) car construction, (4) education of the public, and (5) proper medical care.

As coroner of a small county of 80,000 population, I have tried to reason "the why of accidents" in this locality. Contrary to most people's belief, alcohol and too fast driving are not the chief causes. The usual cause is lack of proper judgment on the part of the driver. Judgment depends on the condition of the driver, the condition of the road, road markings, construction of the car, the weather and an estimate of the speed of an approaching car.

In the fatal accidents of this county I have noted the part of the car that I thought responsible for the accident. If all coroners would report such observations to an American Medical Association committee, I believe that, through recommendations, the automobile death toll in the future might be reduced in place of gradually rising higher and higher.

The following suggestions are based on my personal study of accidents resulting in death in Linn County, Iowa, during the past four years.

Compulsory Driver's Test After an Accident.—The driver in an accident case should be compelled to take a driver's test. The committee might advise all states to frame a law making it compulsory for any driver involved in an accident to take another driver's test before driving a car again. Those failing to pass should be refused a new license until the defect in the car is corrected or the driver's abnormality is properly remedied.

Road Markings.—Knowing that many drivers have defective vision—not properly corrected—and that persons with good vision often cannot read letters of 6 inches through dirty windshields off the side of the road when traveling in a car at 40 miles an hour, I suggest that the signs for traffic safety should be on the pavement, directly in the lane of best vision. No fatal accident, which any sign could prevent, happens when snow covers the pavement, the only objection to "on pavement" signs.

Safer Car Construction.—Desiring more safety for myself and family I shall herewith order the first 1941 popular priced car (any make) constructed according to the following safety ideas.

1. Bumper All Around: A bumper running entirely around the car (removable section to change tires). In most fatal

accidents the bumper of one car catches into the front or rear wheels of the other car and both turn over, or the end of the front bumper is pushed into the front wheel and the car darts off the road.

2. Turtle or Helmet-Shaped Body: Artists have streamlined the tops of cars, but the bottom still has protruding fenders and door handles. The body should be brought out to the bumper on the sides at the bottom so that the fenders are entirely beneath the body. The running board—if any—should also be covered by the body of the car. Door handles should be hinged and dropped into a well in the door.

3. Knock Out Windshield: With safety glass in the windshield, the doctor now sees severe head and neck injuries. The windshield should be so designed that a force of 50 pounds from the inside would loosen the entire windshield without breaking it.

Other desirable features are the steering wheel constructed of material that will bend but not break. There should be no sharp corners on the instrument panel. A strong support should be placed behind the engine to keep the engine from being pushed back against the front seat in case of collision. There should be no sharp ornaments near the front of the car.

B. L. KNIGHT, M.D., Cedar Rapids, Iowa.

Coroner of Linn County.

THE ERYTHROCYTE SEDIMENTATION TEST

To the Editor:—In a recent issue of THE JOURNAL (September 2, p. 942) appeared an editorial on the technic of the erythrocyte sedimentation test. In this editorial an article by Hambleton and Christianson (*Am. J. M. Sc.* 198:177 [Aug.] 1939) was cited in which the authors concluded that the "most commonly used sedimentation technic, without involving complicated corrective procedures, is the most valuable for clinical purposes." The editorial closes with the remark that "this furnishes welcome news to the vast majority of those using the blood sedimentation test in their office and hospital work."

Of course, any report which purports to simplify the technic of a laboratory procedure to such an extent that the general practitioner can carry out the test in his office is welcome news to him and also to the technicians who must do the test. Unfortunately, in most cases the so-called simplification entails the omission of vital steps in the procedure, and this seriously detracts from the reliability of the results. In the case of the apparently simple sedimentation test there are many factors which must be taken into account if results worth the effort are to be obtained.

In an article on the sedimentation rate of erythrocytes, Ham and Curtis (*Medicine* 17:447 [Dec.] 1938) have indicated some of the technical factors responsible for variations in the results obtained in tests made on a single specimen of blood, based on a review of the literature and careful experiments carried out by themselves. The following are some of the points in the technic which affect the sedimentation rate: 1. The rate has been found to be more rapid at higher temperatures. 2. If the tube is inclined away from the vertical, the rate is considerably increased. 3. Other things being equal, the sedimentation rate is higher for lower concentrations of the erythrocytes.

For an understanding of the significance of the results of sedimentation tests, it is essential to know on what properties of the blood the rate of sedimentation depends. It is obvious that the greater the difference in specific gravity between the red cells and the plasma, the more rapidly will the cells settle.

On the other hand the higher the viscosity of the plasma, the more delayed will be the sedimentation of the cells. Finally, since the larger the size of the particles settling in a medium the more rapidly does sedimentation occur, if the red cells are clumped in rouleaux the rate will be increased.

It is evident that an increased sedimentation rate need not in every case signify the presence of an infection or a proteolytic process, nor does the rate depend on a single specific substance in the blood, although it has been shown that a definite correlation exists between the rate and the fibrinogen content of the plasma. For example, the ingestion of large amounts of water would decrease the specific gravity of the plasma and also its viscosity, and in that way might give rise to an increased sedimentation rate. In this connection a report by Ride, Ling, Lim and Cheng (*Caducues* 17:175 [Nov.] 1938) on the sedimentation rate in cholera is of interest. These authors observed that during the acute stage of the disease, on account of the large loss of water through the bowels, the viscosity of the blood is so greatly increased that the sedimentation rate is considerably reduced. When the patient begins to recover, the normal viscosity of the blood is restored and the rate is increased. Therefore in this disease one has the reverse of the usual state of affairs: the rate increases instead of decreasing as the patient improves.

With regard to the technical aspects, it is essential that care be taken to place the sedimentation tube in a perfectly vertical position and that all tests be carried out at the same temperature. With regard to the importance of the latter precaution I shall cite some unpublished experiments carried out with Barbara Fisk and Claire Edelman. Tests were made on a series of healthy blood donors by the technic of Wintrobe and Landsberg. The tests were set up in duplicate, one set at room temperature (in our experiments this varied between 68 and 73 F.) and the other at body temperature (98 F.). It was found that in practically every case the rate at body temperature was about two and one-half times as high as the rate at room temperature. For example, when the rate at room temperature was 2 mm./hour, the rate at body temperature was 5 mm./hour, and in another case in which the rate at room temperature was 16 mm./hour the rate at body temperature was 37 mm./hour. On the other hand, in the refrigerator the rate is considerably less than at room temperature. While under ordinary conditions room temperature should not vary greatly, on hot summer days or in warm climates it is necessary to make allowance for the effect of temperature on the test.

With respect to the importance of the erythrocyte concentration, Ham and Curtis point out that the red blood cells in settling displace the plasma, causing a current in an upward direction, and this in turn retards the sedimentation of the cells. The higher the concentration of red cells the more pronounced is this reverse current. To illustrate this I shall describe one of a series of experiments carried out by me with Fisk and Edelman. A blood with a hematocrit of 0.50, having a sedimentation rate at room temperature of 4 mm./hour, was centrifuged and the plasma and cells were separated. Then only enough cells were resuspended in the patient's plasma to give a hematocrit of 0.32. The sedimentation rate under these conditions was 34 mm./hour. In anemias the concentration of red blood cells is low, and, since in addition in severe anemias the viscosity of the plasma is usually decreased, there would be two factors militating to increase the sedimentation rate even in the absence of any additional pathologic condition. Therefore, if no correction is made for erythrocyte concentration, the results of the sedimentation test are apt to be misinterpreted.

A. S. WIENER, M.D., Brooklyn.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LATENT SYPHILIS—HEMATURIA IN SYPHILITIC PATIENT

To the Editor:—A man with syphilis still has a 4 plus reaction to Kahn, Kline and Wassermann tests after a year's regular treatment. For the past five months there has been a hematuria with from 2 to 30 cells per high power field. He is a railroad worker, aged 35, of excellent general appearance, a weight of 186 pounds (84 Kg.) and a height of 5 feet and 10 inches (178 cm.). There is no history at the time of the original infection. He has no children, and his wife has had three negative Wassermann reactions and three physical examinations with negative results since he has been under treatment. Wassermann, Kahn and Kline reactions were 4 plus on Oct. 27, 1938, at which time his only complaint was "canker sores" in his mouth. No dark field examination was made. He received a half dose, 0.3 Gm., of nearsphenamine (first dose) intravenously, followed by 0.3 Gm. and 0.45 Gm. of nearsphenamine in weekly injections for a total of eighteen doses. During the same period he has received 0.2 Gm. of bismuth subsalicylate once a week for a total of seventeen doses. Since then he has received a weekly injection of nearsphenamine or bismuth (five of nearsphenamine and then five of bismuth) since the hematuria was discovered. To date he has had a total of thirty-two nearsphenamine and thirty-four bismuth injections in eleven months of treatment. At about the time of the fifth nearsphenamine injection he became violently ill several hours after his treatment, with chills, vomiting and headache. Previously he had had no reaction whatever except that one injection of nearsphenamine had been accompanied by local irritation. The three violent reactions did not occur chronologically. Sterilization of instruments, qualities of supplies and dietary control, before and after the nearsphenamine had been given, were carefully checked, and I felt were not the cause of his reactions. About February, after he had received fifteen nearsphenamine injections, there appeared a small series of painless moist ulcers about the size of a match head at the circumscribed edge of the penis. These disappeared with the use of a dusting powder made with a mercury base. No dark field study was made. There has been no recurrence of any lesions of the mucous membrane. There has been not even a mild reaction with the rest of his intravenous therapy. He has gained about 30 pounds (14 Kg.), looks well and has never felt better in his life. Blood pressure has been and is normal (125 systolic and 75 diastolic). A flat roentgenogram of his abdomen shows no stones of the kidney, ureter or bladder. Hematuria was first observed after about twenty-five nearsphenamine and bismuth injections. At that time he had a bilateral backache in the kidney region. He had from 10 to 20 pus cells in the first specimen with a 3 plus reaction for blood. He gave a history of a recent head cold, accompanied by severe backache. I do not know whether this preceding respiratory infection had any connection. At any rate he was cut down to one injection a week, in series of five. We were unable to discover any increase or decrease in hematuria following the bismuth or the nearsphenamine interval. I am unable to decide, because of the hematuria and the remaining 4 plus Wassermann reactions, what I can best do for him. I have not made a spinal fluid Wassermann test but planned to do so before discharging him. He understood from the start that he would probably need treatment for one to one and a half years. I should greatly appreciate counsel as to further treatment of this man. In a recent series of 500 Wassermann tests on employees of an industrial plant, I found among those with positive reactions about six with 4 plus Wassermann, Kahn and Kline reactions who had had previous treatment to the point of becoming Wassermann negative—some as long as twelve years ago. They were all symptom free on careful physical examination. I acknowledge the need for individualization, but what general program would you start with and how long would you treat them after their Wassermann reactions are negative again?

M.D., Indiana.

ANSWER.—This question resolves itself into three parts: first, the management of syphilis in the patient in question; second, the hematuria of the patient, and third, the general treatment of patients with latent syphilis who were seronegative as a result of previous treatment but are now seropositive.

1. No definite conclusions can be reached as to the stage of syphilis in the patient described. The supposed "canker sores" in the mouth in October 1938 and the penile lesions in February 1939 might conceivably have been early and treatment-resistant syphilis, though this cannot now be proved since no dark field examinations were made. On the other hand, it is much more likely that the "canker sores" represented an ordinary aphthous stomatitis and the penile lesions herpes progenitalis and that they are therefore of no value in dating the infection in the patient. The fact that the wife is normal suggests that the patient had syphilis at least five years before his marriage to her, the date of which is not given. His physical examination is not completely described, though the inquirer apparently assumes that the syphilitic infection is latent.

No opinion whatever can be expressed as to the adequacy of treatment given so far or as to the type of treatment still to be given until the patient's spinal fluid is examined. The inquirer states "I have not done a spinal fluid Wassermann test but planned to do so before discharging him." It cannot be too frequently emphasized that in the treatment of patients with late syphilis of any type—latent or otherwise—the spinal fluid should be examined early, not late, and if possible at the start of treatment. If the spinal fluid reaction is positive, treatment is usually of a different type and always of a different intensity than if the spinal fluid is normal. It goes without saying, moreover, that a spinal fluid Wassermann test is not adequate and that a proper examination of the spinal fluid includes cell count, quantitative protein estimation, quantitatively titrated Wassermann test with amounts ranging from 0.1 to 1.0 cc., and a colloidal test, gold, mastic or benzon.

It is immediately necessary therefore to test the spinal fluid. If this is normal and if the results of careful physical examination with particular reference to the central nervous system and cardiovascular apparatus, plus results of fluoroscopic and teleroentgenographic examination of the cardiovascular stripe (the latter including the left anterior oblique position) are normal, it may be assumed that the patient has now had enough treatment for syphilis and this may be stopped, regardless of his positive serologic reactions. If, on the other hand, the spinal fluid is abnormal or if physical and x-ray examination show abnormalities in the nervous system or cardiovascular system, further treatment is indicated, but its type and amount cannot be determined without more information than is supplied.

2. Much more important at the moment than the patient's syphilitic infection is the hematuria, the cause of which is by no means clear on the basis of the information provided. It may be safely assumed that this is not due to syphilis and that it is almost surely not due to antisyphilitic treatment. The head cold accompanied by backache immediately preceding the discovery of hematuria suggests that the latter may be due to an acute glomerular nephritis or an acute or subacute pyelonephritis. The investigation of the hematuria is, however, hardly complete with a flat plate of the abdomen only. Is there any edema? What are the results of renal function tests? Does intravenous pyelographic study show any abnormalities? If no other cause for the bleeding can be discovered cystoscopic and retrograde pyelographic examination should be carried out in order to determine its cause.

The importance of definition of the cause of the hematuria is so great as to suggest that temporarily, and regardless of the outcome of spinal fluid examination, treatment for syphilis should be suspended until the complicating disease is more accurately defined.

3. The third question deals with the general problem of the management of patients with latent syphilis treated to the point of seronegativity but later, after years of subsequent observation, showing positive serologic reactions of the blood. The question is based on the prevalent custom of treating patients with latent and late syphilis on the basis of serologic data. The successful treatment of latent syphilis at the time of the original diagnosis does not depend on reversal of the serologic reaction to negative but depends instead on the administration of an arbitrary amount of treatment determined by the clinical outcome in large series of patients followed over long periods. One needs closely to keep in mind the purpose of treatment of latent syphilis, which is not the treatment of a blood reaction but instead treatment administered prophylactically to prevent the development of disease as opposed to laboratory evidence of infection. On the basis of present knowledge, eighteen months of continuous antisyphilitic treatment is adequate for the patient whose syphilis of more than four years' duration is genuinely latent. Whether or not treatment should be terminated at this point or carried further has nothing whatever to do with the outcome of the blood test. Whether or not it should be subsequently resumed depends not on the outcome of the qualitative serologic test per se, but instead, and this is much more important, on the basis of the possible development of clinical evidence of disease or on a high titer serologic relapse as evidenced by repeated quantitative blood tests.

In the particular circumstance described here a patient treated twelve years ago then became seronegative and is now found to be seropositive. This circumstance almost surely depends not on any change in the patient himself but instead on increased sensitivity of the serologic tests employed now as contrasted to those employed twelve years ago. The question then becomes: Shall one resume treatment on this patient because laboratories now are better than they were twelve years ago? This question answers itself by virtue of its own absurdity.

QUERIES AND MINOR NOTES

2081

In other words, if the six patients mentioned in the inquirer's last paragraph were adequately treated for latent syphilis some years ago; if they now show no physical evidence of disease, and if results of their spinal fluid examinations are all normal, it may be inadvisable to give any treatment. It is, however, advisable to continue to perform blood tests at periodic intervals by a quantitative technic. If the reagin titer in the blood of these patients is rising, the desirability for treatment may again become apparent.

Parentetically, this is the only present known use for quantitative titration of serologic tests, namely, for the follow-up study of patients who have been placed on probation.

INFLUENZA IN HORSES AND MAN

To the Editor:—A man states that he bought a horse which had influenza (or shipping fever) and that he contracted influenza from this horse. Will you kindly let me know whether the "flu" is communicable from horse to man? If there is any literature regarding this subject I would appreciate it if you would refer me to it.

S. H. Anderson, M.D., Red Wing, Minn.

ANSWER.—The impression that equine influenza is related to influenza in man is old. Numerous writers have called attention to the synchronous relationship of influenza in horses and epidemics of influenza in the human population. According to A. J. Williams (Analogies Between Influenza of Horses and Influenza of Man, *Proc. Roy. Soc. Med.* 17:47 [June] 1924) there has been no convincing evidence that the equine disease is transmitted to handlers, and in the equine epidemic of 1872-1873 there was no increased amount of influenza in man. Equine influenza has not been thoroughly placed on an etiologic basis, although hemolytic streptococci have been found in abundance in most outbreaks. Waldmann has studied the epidemic cough of horses which resembles what is called equine influenza and has reported the isolation of a filtrable virus which combines with hemolytic streptococci to produce a severe form of the disease. There is no evidence that this virus bears any relation to human influenza virus.

It would appear that much of the answer to this question depends on whether the correctness of the diagnosis of horse influenza is important. Other equine diseases, such as encephalomyelitis, do attack human individuals.

POSSIBLE TULAREMIA AFTER CATFISH PRICK

To the Editor:—On May 31, 1939, a 16 year old boy came to my office with the complaint "I was stuck by a catfish yesterday and today I feel terrible and my arm hurts." Further questioning revealed that it was the ordinary type of catfish and that the patient was having sharp shooting pains through the right arm and shoulder. He had been feeling well prior to the accident. The past and family histories were essentially irrelevant. The temperature was 101 F., the pulse rate 100 and the respiratory rate 22. There was an area of redness about the size of a half dollar over the right costoclavicular junction. The axillary glands were palpable or tender. He was given symptomatic treatment, i. e., powder of ipecac and opium to induce diaphoresis, forced fluids, bed rest, and hot packs to the site of puncture. On July 10 he received a dirty puncture wound on the sole of the left foot and was given 1,500 units of antitetanus serum in the left deltoid. At this time he was still returned because of difficulty in using the right shoulder. On August 23 he had a small foreign body discovered over the right arm, particularly in the junction was extracted and found to be a sharp bony spine about one-fourth inch long. He was referred to an orthopedist and on September 13 I received the following report: "The right shoulder shows moderate atrophy of the supraspinatus and infraspinatus muscles. There is marked weakness of the serratus magnus with winging of the scapula. The right shoulder is lower than the left. The deltoid, biceps and pectorals are not involved." I should appreciate having the following questions answered: Is any catfish toxin known which might have produced this virus on being "horned" by a catfish? Could the antitetanus serum possibly have had any such effect? (The skin test was negative and he had mild serum reaction about a week later for which he did not report back.) What treatment would you recommend?

M.D., Ohio.

ANSWER.—Catfish in certain sections of the country have become contaminated with *Bacterium tularensis*. One specific case of human infection from the prick of a catfish fin has been reported by D. H. Miller in Wichita, Kan. In this case the fish was caught in the Neosho River, Morris County, Kan. Miller learned that at least three other persons, after being pricked by fins of fish of the same catch, developed a disease similar to that of his patient, which was proved to be tularemia. He was further able to obtain reports that rabbits with so-called rabbit fever had been seen to fall into the river and drown and that the river water contained numerous rabbit carcasses.

Although in the case reported in this query there was an extremely short incubation period, since the patient stated that the injury from the catfish occurred on the day preceding his

application for medical attention, the temperature, pulse and area of redness in the region of the shoulder are quite compatible with a *Bacterium tularensis* ascending infection from the catfish injury. Infection which may have localized in the right costoclavicular junction may well have resulted in considerable atrophy from disuse of the shoulder.

No evidence has been found which would justify any assumption that there is a catfish toxin. It is equally unlikely that the antitetanus serum produced the disability. The course of the illness, as described, is not compatible with a diagnosis of anterior poliomyelitis and there have been no cases reported in which the inoculation with poliomyelitis virus occurred in any manner similar to this. It would be well to have a serum agglutination test for tularemia, since this test continues positive for a long time after the infection itself has subsided. If tularemia cannot be proved and the diagnosis of paresis of the serratus magnus with winging of the scapula is correct, this arm should be splinted in a position of 90 degrees abduction at the shoulder and 45 degrees external rotation. This airplane type of splint should be continued for not less than three months, with the patient receiving physical therapy consisting of light, heat and light massage two or three times a week, if this type of treatment is available. Exercises for the weak muscles should be carefully supervised and should not be started until from four to six weeks after applying the splint.

SLOW FETAL HEART RATE

To the Editor:—What explanation would you give for a slow heart in this case? The rate at fetal heart tones at every examination was 76 a minute with an occasional dropped beat. The tones were loud. One hour after birth the tones were regular and of good quality and the rate was 78; since then it has been 80. Once during sleep it was 66 a minute. The baby is developing normally and is breast fed. Physical examination does not reveal anything wrong with the heart as to size or murmurs. The mother's heart rate during pregnancy and now is 78 to 80. She had an attack of cardiac angina at the seventh month that required morphine, and there is a history of an attack one year ago. Can you have an opinion on such limited information? Has any case of such a low pulse in a fetus or newborn infant been reported?

W. I. Devers, M.D., Pierce, Neb.

ANSWER.—A fetal heart rate of 80 or less is rare late in pregnancy. It is quite common to find a temporary slowing of the heart beat as a result of some interference with the fetal circulation, but as a rule the rate returns to normal in a period of hours. To have such a condition persist after delivery of the baby is extremely rare. In a maternity service which has delivered well over 50,000 babies there is no accurate record of such a case. One must assume that there is some congenital anomaly involving the sino-aortic node similar to the condition which is responsible for heart block in the adult. Cardiac congenital abnormalities are not rare, although this particular abnormality is unusual. The baby should be studied carefully if possible by means of the electrocardiograph. In the event that no unusual organic pathologic condition can be determined no therapy is indicated.

PHYSIOLOGY OF TICKLING

To the Editor:—Why is it that the vast majority of people are sensitive to tickling, especially in the axillae, when the tickling is done by a second party, yet are completely unaffected when they do it to themselves? Can the explanation be purely psychologic? What is the physiology of tickling of the skin and the common nervous effect?

M.D., Saskatchewan.

ANSWER.—Most people have what is known as a deep tickling reflex, which is brought about by peripheral stimuli not self induced and results in laughter. It is elicited by stimulation of the end organs of certain large tendons or aponeuroses, or of the periosteum of certain large bones, especially the ribs. The areas in which such pressure produces laughter are the lateral walls of the thorax, axillae, abdomen and iliac fossae. The pressure must be done usually by another individual and it induces a tonic contraction of the neighboring muscles together with a withdrawal from the stimulus and laughter. At times weeping may occur. The fact that laughter usually does not occur when the stimulation is self induced is due to two factors. One is that the individual is not prepared to laugh (conscious inhibition) and the other is that there is no decrease in the tone of the involved musculature that is being stimulated. Certainly laughter temporarily diminishes the tone of all the voluntary muscles. It is entirely possible to overcome the effects of the deep tickling reflex by keeping the involved areas completely rigid. The pathway of the deep tickling reflex is peripheral nerve, posterior horn, posterior column and ascending tracts to the thalamus. There is also a superficial or cutaneous tickling or itching effect. This effect is a cutaneous sensation elicited either by the individual himself or by an outsider. It is pro-

duced by touching with a feather, moving the hairs, and the like. This sensation may continue for some little time after the stimulus has ceased and it can be relieved by vigorous rubbing or scratching of the involved part.

BRAKE FLUID AND TIRE POWDER

To the Editor:—Have you any information as to the composition and possible irritant qualities on the skin of the modern brake fluid used in automobiles? I understand that contact is sometimes irritating. Also is the powder used on new tires irritating to some skins?

Stanley Crawford, M.D., Pittsburgh.

ANSWER.—The composition of brake fluids is secret with automobile manufacturers and varies with the different makes of automobiles. Many contain esters of fatty acids, tetrahydrofurfuryl alcohol and other constituents which might be expected to produce dermatitis in susceptible individuals.

The powder used on new tires is usually composed of talc or soapstone and should not be a chemical irritant to the skin. However, if the powder is not finely ground there may be some sharp crystals remaining in it which may penetrate the skin and cause dermatitis. Whiting, which consists principally of calcium carbonate and a slight amount of silica and the oxides of iron and aluminum, is used extensively as a filler for rubber products and may bloom out of the rubber in the form of a powder. This should not irritate the skin. However, irritant materials such as antioxidants and accelerators may also bloom out of the rubber, and these substances will cause dermatitis in sensitive individuals. A chemical analysis of the powder on the rubber is necessary to determine whether it is soapstone put on to prevent the rubber from sticking or whether it is a "bloom." For further information on rubber and blooms the inquirer is referred to Skin Hazards in American Industry (Public Health Bulletin 215, part 1, pp. 1-10).

MYXEDEMA AND COLD EXTREMITIES

To the Editor:—A 70 year old multipara passed the menopause at 45. At 50 she was treated for myxedema because of increasing weight and a generalized cold feeling. The basal metabolic rate was extremely low. She took thyroid and corpus luteum by mouth for twenty years with benefit. In December 1938 she developed intermittent attacks of cold feet and legs with numbness of some of her toes. No ischemia or cyanosis was present. Now she has periods of extreme coldness of one or the other lower extremity, alternating with a sensation of heat in the same places. There may be places as large as two hands in various parts of the body, usually in the extremities, which will be extremely cold. Even during the hottest nights she sleeps at times with her legs wrapped in blankets and with hot water bottles applied. Frequently her whole torso will sweat profusely when her extremities are cold. At times she is symptom free for short periods. Attacks of cold in the extremities may last ten days. Attacks of heat in the extremities usually are of less than one day's duration. Except for a metabolic rate of -27, the physical examination of this patient is essentially negative. The blood pressure is 130 systolic and 80 diastolic; the urine, temperature, and blood count, reflexes and tactile sense are normal except for intermittent numbness of the great and adjacent toes of both feet. There seems to be adequate peripheral circulation as expressed by normal pulsating dorsalis pedis arteries. Can you suggest a diagnosis or means of arriving at one? Can you suggest treatment?

M.D., Texas.

ANSWER.—A patient with myxedema can scarcely be considered to have adequate treatment with a basal metabolic rate of -27 per cent. The first step in solving the problem is to raise the metabolism gradually to normal by slowly increasing the dose of thyroid. A word of caution is necessary because the patient is 70 years old and, therefore, more likely to have disease of her coronary arteries than younger patients. The dose should not be increased more than $\frac{1}{2}$ grain (0.03 Gm. U. S. P. thyroid) at a time and increases should not be made more often than once in six weeks.

INTRAVENOUS PARALDEHYDE

To the Editor:—Have you any information on the intravenous administration of paraldehyde? A friend of mine is using it in 2 to 3 cc. doses and believes it to be safe and effective in acute alcoholic intoxication.

M.D., California.

ANSWER.—The intravenous injection of from 2 to 3 cc. of paraldehyde would be entirely safe from the standpoint of dosage: Nitzescu and Iacobovici (*Presse méd.* 42:331 [Feb. 28] 1934) reported the use of from 0.15 to 0.21 cc. paraldehyde per kilogram of body weight by intravenous injection for the production of general anesthesia, and this would amount to from 10 to 15 cc. for an adult of 70 Kg. The only question concerns flocculation of the blood and consequent flocculation shock. They employed a 6 to 8 per cent solution of paraldehyde in 5.66 per cent of dextrose, injected at the rate of from 15 to 20 cc. a minute. This solution gives a distinct opacity

if shaken with an equal volume of protein solution (egg white diluted with 10 parts of water). However, the opalescence is slight and would probably not give trouble if the injection was made slowly. Paraldehyde requires 8 parts of water for solution, and if undiluted paraldehyde is shaken with an equal volume of the protein solution there is immediate precipitation. It would seem therefore that there is risk of serious flocculation shock if undiluted paraldehyde is injected into a vein, even if this is done slowly. Rectal injection of equal volumes of paraldehyde and olive oil, or of a 10 per cent solution in physiologic solution of sodium chloride, gives prompt sedation and would seem preferable to the intravenous injection.

DISCHARGING BREASTS

To the Editor:—A woman aged 26 has late latent syphilis with intermittent therapy. She suddenly developed a thin greenish discharge, which exudes and can readily be expressed from her nipples. Her mammary glands have also become enlarged within the last few months. An increase of 14 pounds (6.4 Kg.) in weight since May is also apparent, as is a sluggishness of her activity. The basal metabolic rate has not been determined. There has been oligomenorrhea and irregularity of the menses for the past three months. Erythema has been noticed over the hypothermic eminences of the palmar aspect of the hands. Approximately one and one-half years ago I performed an oophorectomy (unilateral), salpingectomy (bilateral) and appendectomy on this patient. She made an uneventful recovery. I realize that the syphilitic infection should be cured for. The other symptoms point to an endocrine imbalance, probably on an ovarian basis. The remaining ovary has undoubtedly failed because of vascular insufficiency (development of adhesions) or cystic degeneration as a result of the past gonorrheal infection for which the pelvic operation was done. Do you agree that the greenish discharge is of endocrine origin? M.D., Illinois.

ANSWER.—The secretion from the breasts may have an endocrine basis, but a microscopic examination should be made to be certain that the secretion does not contain blood. It is assumed that physical examination of the breasts revealed no abnormalities. The patient should have at least one basal metabolic test. Because of the recent sudden gain in weight, the patient should be placed on a reducing diet and should be given a small amount of thyroid even if the basal metabolic rate is normal, but certainly if it is lower than normal. Likewise, thorough and persistent antisyphilitic therapy should be instituted. The remaining ovary may not function properly because its circulation was interfered with mechanically by the operation rather than by adhesions and the gonorrheal infection. A bimanual examination should be made to rule out a pelvic disturbance, which occasionally is associated with a discharge from the breasts.

ELECTRIC OPHTHALMIA

To the Editor:—What is the best treatment for the extremely painful irritation of the eye caused by exposure to the glare of an electric welding torch? I have seen a number of cases lately and was usually forced to use morphine injections when local application of epinephrine and phenacaine hydrochloride, ice pack and avoidance of light were not satisfactory.

F. C. Kotzenstein, M.D., Salem, Ill.

ANSWER.—The condition known as electric ophthalmia, snow blindness or Klieg eye consists of a superficial injury to the corneal epithelium by ultraviolet rays of less than 3,300 angstroms. The superficial nerve terminals of the cornea are exposed by the death and desiccation of superficial epithelium and consequently the pain will persist until the epithelium has regenerated. Complete tight bandaging of both eyes and the local use of anesthetics usually suffices to control the pain, but, as the writer says, the use of morphine is at times necessary. That procedure is not contraindicated.

TERMITE SPRAY AND ORTHODICHLOROBENZENE

To the Editor:—Can you give me any information as to what is used in the commercial spray for termites and also as to any effects reported on the eyes of those employed in its use.

S. M. Gotes, M.D., Monticello, Ark.

ANSWER.—Orthodichlorobenzene is probably the agent in question. In connection with its use in combating termites the following statement appears in "Injury to Buildings by Termites" (United States Department of Agriculture, leaflet 101, June 1936). "The cautions to be observed in the use of this chemical are not to let it come in contact with the face and hands, as it burns slightly, and it is distinctly painful if it gets into the eyes. In applying it to a closed space beneath the building, the operator should not remain too long subject to the fumes, and it is desirable to secure as good ventilation as possible while applying the chemical."

For further and more detailed information concerning this chemical, reference might be made to "Dermatitis from Orthodichlorobenzene" (Queries and Minor Notes, *THE JOURNAL*, September 9, p. 1053).

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, November 25, page 1985.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 12-14. Part III. Chicago, Jan. 16-18. New York, January 15-17. Registration closes Dec. 9. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Written. Part I. Various places throughout the United States and Canada, March 28. Oral. Part II. New York, June 10-11. Applications must be received 60 days prior to examination. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: November 1940. If sufficient candidates are received before March 1, there will be on June 10-14. Sec., Dr. C. Guy Lane, Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Written. Various cities of the United States and Canada, March 2. (The only written examination in 1940.) Oral. New York, June 8-10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, June 3-5. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics, Seattle, June 2. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 18-19. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklm, 102-110 Second Avenue S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Michigan June Examination

Dr. J. Earl McIntyre, secretary, Michigan State Board of Registration, reports the written examination held at Ann Arbor and Detroit, June 13-14, 1939. The examination covered fourteen subjects and included 100 questions. An average of 75 per cent was required to pass. Two hundred and five candidates were examined, all of whom passed. The following schools were represented:

Colorado July Examination

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, July 10-12, 1939. The examination covered eight subjects and included sixty-nine questions. An average of 75 per cent was required to pass. Fourteen candidates were examined, eleven of whom passed and three failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College	(1938)		81
Creighton University School of Medicine.....	(1939)		80.3
McGill University Faculty of Medicine.....	(1934)		82.3
Osteopaths*	75.5, 78, 79, 80, 80.3, 82, 83.3,		83.3
FAILED		Year Grad.	Per Cent
Osteopaths*	73.5, 73.5, 74.5		

* Examined in medicine and surgery.

Pennsylvania July Examination

Dr. James A. Newpher, secretary, State Board of Medical Education and Licensure, reports the examination held at Philadelphia and Pittsburgh, July 5-8, 1939. Five hundred and twenty-five candidates were examined, 520 of whom passed and five failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed

Book Notices

The Building of a Nation's Health. By Sir George Newman, G.B.E., K.C.B., M.D. Cloth. Price, \$6. Pp. 479, with 9 illustrations. New York & London: Macmillan Company, 1939.

Here is a complete and detailed account of the history and growth of the machinery charged with the maintenance of health in Great Britain. The author, Sir George Newman, was chief medical officer to the board of education from 1907 to 1935 and chief medical officer to the ministry of health from 1919 to 1935. The book is therefore authoritative because of his first hand association with the work it discusses. It provides also, however, an accurate history of the beginnings of the school medical service, of health insurance and of the ministry of health in Great Britain.

It is found on study of this book that English medicine and public health are governed by a variety of agencies and that it has been difficult, if not impossible, to correlate these activities with newly developed endeavors. Thus, in Great Britain as in this country, there are many different agencies involved in the care of the sick and in the prevention of disease, and the health insurance system has perhaps helped along some lines but interfered in others. Indeed, Sir George points out that the health insurance system is a practitioners' service only, without a consultative or specialist element, without laboratories or nurses or hospital accommodations for observation, and quite ineffective in developing cooperation between the insurance committees and the health authorities. There seems to be little doubt that the health insurance act has been advantageous to the medical profession and perhaps even good for the people, since it provides them with a better medical service than they had formerly, but the scheme is neither complete nor perfect. Sir George says that its medical scope is still too restricted; there is observable too great a tendency to the "bottle of medicine" treatment as palliative, and the accurate diagnosis, effective treatment and actual preventive measures are sometimes conspicuous by their absence. He believes that some thousands of the eight million patients dealt with under this act are not really satisfied "not because they do not get well but because they do not receive the attention which they expected." He then continues: "Every unsatisfied patient is, de facto, a criticism of his doctor. In private practice that is his own affair; but in a state system of practice, in which the treatment has been already paid for, it becomes a breach of contract, damaging to the doctor, the service and the state. Again, public opinion declares that a substantial number of practitioners are careless, even negligent, in their insurance practice, that some panels are too large to ensure adequate attention to the individual patient, that the sickness and 'incapacity' certificates are granted too liberally, that 'multiple surgeries' are disadvantageous, and that large 'firms' of insurance practitioners exclude 'freedom of choice' of doctor by the patient. The approved societies have more than once complained of excessive certification of 'incapacity' (resulting in undue payment of cash benefit) and excessive prescribing. Both of these complaints were fully investigated by the ministry (1927-1931) and both were proved to be justified."

In the final section of his book, entitled "Whence and Whither?" Sir George provides an analysis of the chief gains made in the field of preventive medicine. The first three practical health movements were for sanitation and sanitary cleanliness, the establishment of primitive hospitals, and the practical knowledge of the contagiousness of disease and the necessity for quarantine. Then came water supply. Next came notification of infectious diseases and registration of the cause of death. Next came vaccination for smallpox and thereafter control of the wholesomeness of food, meat and milk, reform in housing, improvement in lighting, ventilation, cleanliness and reduction of overcrowding. The great problem remaining for legislative control, he says, was provision of effective medical treatment of the sick. As evidence of the accomplishments, Sir George analyzes the sickness and death rates so far as they are available, and he cites these benefits to prove that the intervention of the state in behalf of national health has had a beneficial effect. He fails, however, as a scientist should, to take account

of the fact that similar, if not better, results have been achieved in some nations where the state has not intervened to nearly the same extent.

He feels that national health depends first on knowledge of the science and art of medicine and then on its social application by the medical practitioner, by the state and by the people of that state. What is still needed is better application by the state and wider usage by the people. He makes a great plea for education of all the people in the science and art of health.

L'examen du malade: Guide clinique de l'étudiant et du médecin. Médecine, chirurgie, obstétrique, neurologie et spécialités. Par MM. P. Delmas et al professeurs à la Faculté de médecine de Montpellier. Second édition. Paper. Price, 45 francs. Pp. 365. Paris: Masson & Cie, 1939.

It seems that the most cogent criticism of the manual is to be found in its subtitle: "Clinical Guide for Students and Physicians in Medicine, Surgery, Obstetrics, Neurology and Specialties." In other words, the scope of the compendium, intended primarily for the use of medical students and interns, is to describe history writing in cases belonging either to one of the fields mentioned or to dermatology, pediatrics, otorhinolaryngology, ophthalmology or gynecology. Moreover, the present edition has been enlarged by addition of chapters on psychiatry and endocrinology. The author and his collaborators had no intention of offering a treatise on symptomatology or diagnosis and limited themselves to showing the intern how to interrogate and examine the patient and to record the results. The concise epitome has been written in a simple, succinct manner but the enormous field covered and the small format of the book exclude an adequate discussion of many subjects. Perusal of numerous sections chosen at random reveals that much essential information has been omitted. For instance, in the discussion of leukorrhea on page 146 *Trichomonas* infection is not mentioned as the possible source of the vaginal discharge. Not less than ninety-three pages is devoted to the description of normal laboratory observations and indications for various research methods, without mentioning how to perform the tests. Owing to the vastness of the material, only few chapters cover the subject in a more than elementary manner; on the whole, the usefulness of the manual will be limited to beginners, to whom it may prove to be a handy guide.

Psychological Factors in Marital Happiness. By Lewis M. Terman and others. Cloth. Price, \$4. Pp. 474, with 28 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1938.

In this book the authors discuss the marital satisfaction experienced by 2,484 subjects, including 1,133 married couples and 109 divorced couples. The technic used was psychometric. The various chapters describe the psychologic factors in marital compatibility and the development of an index of marital happiness. There are studies of the personalities of happily married and unhappily married people, with special relation to the family background. Then there are four chapters dealing with sexual factors. Here the authors discuss sleeping arrangements, contraceptive technics, sexual complaints and similar matters.

In estimating their index of marital happiness, the authors concern themselves with such matters as customary methods of settling disagreements, regret of marriage, choice of spouse if life was to be lived over, and a complete score based on domestic grievances. The happiness index and the personality tests are also significant. The authors found, for example, that the presence of children often prevents the breaking up of marriage but that it has little effect on the general level of marital happiness. Much nonsense has been written, they say, about the risks entailed in marrying on an inadequate income or marrying out of one's age or educational group. The correlation of income with happiness is zero. The happiest wives are from four to ten years older than their husbands; the happiest husbands are twelve or more years older than their wives. As for religious training, they say that if this was ever a factor in marital happiness it appears no longer to exert such an influence. As to relative mental ability, the most favorable condition is equality or near equality. Marked mental superiority of the husband makes for happiness in the wife but for unhappiness in the husband. Marked inferiority of the husband makes the wife unhappy but does not greatly affect the husband.

The ten background circumstances most predictive of marital happiness are:

1. Superior happiness of parents.
2. Childhood happiness.
3. Lack of conflict with mother.
4. Home discipline that was firm, not harsh.
5. Strong attachment to mother.
6. Strong attachment to father.
7. Lack of conflict with father.
8. Parental frankness about matters of sex.
9. Infrequency and mildness of childhood punishment.
10. Premarital attitude toward sex that was free from disgust or aversion.

Most significant is the conclusion of the authors that sex technics, which many writers regard as the primary key to happy marriage, may be worth cultivating for their immediate sensuous returns but exert no appreciable effect on happiness scores. It is interesting to realize that about 33 per cent of women fail to achieve sexual satisfaction in marriage.

The authors find that the key to happiness in marriage is not to be found in sexual compatibility and, in fact, is no greater than that of the combined personality and background factors and is probably less. It is interesting to note that one of the most important factors is such a small matter as the wife's slovenliness in appearance. This book contains a vast amount of important data and suggestions for physicians who may frequently be concerned with these problems.

Practice of Allergy. By Warren T. Vaughan, M.D. Cloth. Price, \$11.50. Pp. 1,082, with 338 illustrations. St. Louis: C. V. Mosby Company, 1939.

In 1930 the author published a book on allergy and applied immunology, and a second edition came out in 1934. Both those works were planned for physician and patient, but now allergy has advanced so greatly that a volume of almost 1,100 pages is needed to present the subject as it concerns the physician alone. The physician who specializes in allergy must nowadays be not only an internist but also thoroughly familiar with the diseases of the skin and those that affect children and must have more than an ordinary knowledge of the conditions affecting the nose and throat. In addition, he must have a good knowledge of botany, bacteriology and parasitic conditions. In this work the author first presents the history and basis of his subject and then proceeds to diagnosis, food allergies, conditions developed by pollens and by bacteria pharmacology, and the specific allergic diseases. The work is supplemented with a bibliography and an excellent index. An added feature is a collection of excellent portraits of pioneers in this field. The author's personal experience is reflected throughout the book. The records of his cases, supplemented by excellent photographs, make the volume individual beyond most other textbooks in this field. Any physician who wishes to have easily available a complete reference work on this subject will do well to avail himself of what Dr. Vaughan offers. The amount of detailed information is vast and is not available elsewhere under one cover.

Money to Burn: What the Great American Philanthropic Foundations Do with Their Money. By Horace Coon. Cloth. Price, \$3. Pp. 352. New York, Toronto & London: Longmans, Green & Co., 1938.

For some time there has been intense interest in the question as to what place will be occupied in the future by the great foundations established by the multimillionaires of the past. The author begins by describing the development of the various foundations and their relationship to the law. Then he discusses particularly the Carnegie and Rockefeller Foundations, including the General Education Board. Unfortunately, he has depended primarily on the *New York Times* for his information, and therefore much of what he says is colored by the established policies of that paper. A small space is devoted to the Duke Foundation, the Brookings Foundation, the Spelman Fund, the Twentieth Century Fund, Chemical Foundation and others. The chapter called "Public Health and Private Philanthropy" is full of misstatements of fact and inconsistencies and indicates the very casual manner in which the whole book is written. The statement is made that the federal government appropriates less than \$5,000,000 a year for public health, whereas the actual amount spent by the federal government is more nearly \$125,000,000 a year. In

this chapter the author discusses principally the Rockefeller Foundation and the Commonwealth Fund. The discussion of the Milbank Fund is a defense of Kingsbury vs. the American Medical Association. Here the author apparently accepts what has been said by Rorty as gospel and repeats all the unestablished charges relative to boycotts of the Borden Company. Next comes a statement relative to the Kellogg Foundation and the American Foundation. The entire chapter is obviously taken by the author out of the *New York Times*, and the resulting pathologic specimen is just what any physician with a knowledge of genetics would expect. The book ends with a sort of conclusion that multimillionaires give their money to foundations in order to help protect the money that they do not give away. The author apparently believes that the government should take over the foundations in some manner because they are indirectly perpetuating monopolies.

Sleep and Wakefulness as Alternating Phases in the Cycle of Existence. By Nathaniel Kleitman, Department of Physiology, The University of Chicago, Chicago. Cloth. Price, \$5. Pp. 638, with 33 illustrations. Chicago, Illinois: University of Chicago Press, 1939.

Among a mass of literature on sleep published in recent years the book by Kleitman comes as a refreshing, scientific document in the midst of theory, superstition and suggestion. The author, who is associate professor of physiology at the University of Chicago, has done sixteen years' observational and experimental work on this subject. He provides evidence of the functional differences between wakefulness and sleep and discusses the periodicity of sleep and the factors that disturb the sleep-wakefulness cycle. He also discusses states resembling sleep, such as hibernation and hypnosis, and concludes with an analysis of the various theories of sleep. An exceedingly practical chapter deals with the hygiene of sleep. The book is complete with a bibliography and an index. The book is beautifully printed, the style is excellent and the reasoning is sound. The author concludes that cortical dominance is the principal feature in the development of the vertebrate nervous system and is also the determining factor in prolonging the time allotted to the wakefulness phase and in adapting the rhythm of sleep to the diurnal alternation of night and day. He has proved by physiologic experiments many facts which people frequently find out for themselves. For example, if a drowsy person is removed from the influence of light and sound and assumes a horizontal position on a comfortable bed, he will not need anything to produce the onset of sleep. The sleep problem is not solved by the research here presented because there are still many facts that only scientific experimentation can establish, but this volume comes nearer to being a scientific evaluation of all the facts heretofore accumulated than any other work on the subject thus far available.

Künstliche Fiebererzeugung mit Kurzwellen: Kurzwellen-Hyperthermie. Von Dozent Dr. med. habil. Ernst Raab. Boards. Price, 5.50 marks. Pp. 158, with 36 illustrations. Leipzig: Georg Thieme, 1939.

This textbook on the artificial production of fever by means of short radio waves is the first comprehensive work on fever therapy to appear in Germany. The information contained in it is based to a certain extent on personal researches of the author, which have been performed with apparent enthusiasm. The book is divided into two sections: the first deals with the various methods of production of artificial fever and the second concerns the clinical applications of fever therapy. There is a description of the historical developments of artificial fever, a chapter on the production of fever by chemical means and, following this, chapters dealing with the various physical methods of fever production. The use of radiant heat and hot baths is mentioned, and the Kettering hypertherm (hot, humid air cabinet) is described briefly. The author apparently has a wrong conception of this device, since he argues that because it never has been marketed commercially it probably is not a satisfactory apparatus. As a matter of fact, the device was prepared simply as an apparatus to be used in research, and a number of commercial concerns now manufacture appliances which embody its principles.

The author lays particular stress on the production of fever by short wave diathermy, and ample reference is made to the work of American authors. Strangely enough, certain earlier publications in the author's own language, such as those by

Köhler of Geneva and those emanating from the neurologic clinic in Vienna, have not been mentioned by the author. He presents a careful description of the differences between the production of fever by means of the condenser field and the electromagnetic field. Such descriptions previously have been presented not only by Kowarschik in Vienna but also by certain American authors. Although the author admits that he has not employed the method himself, he criticizes the technic of fever production by means of short wave diathermy as employed by certain French authors. Whereas he is naturally enthusiastic about his own technic, which would seem adequate, nevertheless, probably because of unfamiliarity with other methods, he seems to be too critical of certain excellent methods of production of fever. According to the technic of the author of this work, the patient is placed in a fever bag, which is closed by means of a slide fastener and lies on a hammock-like table. The author employs a two tube short wave diathermy machine, the energy output of which is divided into two portions and is conveyed to the patient by means of two coils. The author reports that he has had no severe complications or deaths in about 700 treatments. The systemic temperature of the patient is raised to 40 or 41 C. (from 104 to 106 F.) and is maintained for several hours. The author cites instances in which this technic has been employed in the treatment of patients more than 60 years of age without untoward complications. In a special chapter, physical fevers are compared to artificial fevers produced by malaria. The author is strongly in favor of the use of physical fevers. In the section on clinical uses of hyperthermy by means of short wave diathermy, brief descriptions of the various conditions in which the treatment is considered indicated precede discussion of the treatment.

Whereas, especially in discussing the treatment of certain of these diseases by means of fever therapy, the author rather limits himself, he has drawn freely on the statistical studies of American authors for support of his conclusions. Among the diseases for which fever therapy is recommended are listed cerebrospinal syphilis, gonorrhea, arthritis, multiple sclerosis, chorea, poliomyelitis and neuritis. As the first German textbook on this subject, the volume may be considered a valuable contribution and any one interested in fever therapy will find much of interest in it.

We Didn't Ask Utopia: A Quaker Family in Soviet Russia. By Harry and Rebecca Timbres. Cloth. Price, \$2.50. Pp. 290. New York: Prentice-Hall, Inc., 1939.

This volume comes with an introduction by Walter Duranty, who certainly knows about Russia, and Dr. C.-E. A. Winslow, who knows the authors and who met them at the Hotel National in Moscow in 1936. The book includes the letters of Mr. Harry Timbres, the journal of his wife, and some reference to their children. The authors, who are Quakers, went to Russia to study the system and particularly to look at socialized medicine. Harry Timbres was interested in the prevention of malaria, and shortly after their arrival in Russia they made contacts with Russian health authorities and with Dr. Sigerist. The letters give a clear picture of events in Russia and particularly of the antimalaria work. The journal of Rebecca Timbres reveals much more of Russian habits of mind and of the conditions than do the letters of Harry Timbres. It is interesting to read at this time Litvinov's statement on war and to realize how far Russia has departed from that point of view. There is an interesting letter from the author to Dr. John Kingsbury, in which he points out that the Russian system does not supply any of the element of personal touch which characterizes private practice at its best and also gives his opinion that Russia had better work out the system before America experiments with it. The book reveals also the primitive conditions of living and inadequacy of food which must prevail among the mass of the people. The author and his wife had to use one half of their entire income, while working for the health of Russia, to purchase the limited food that was required by the family. Saddest of all in this work is the description of the ultimate infection and death of Harry Timbres, particularly his refusal to go to the Marburg Hospital after he developed typhus, and his desire to go to the University Hospital at Kazan. This book is revealing in more ways than one on the Russian medical system and on the American interests which would transfer that system to this country.

Secretarial Efficiency. By Frances Avery Faunce. With the collaboration of Frederick G. Nichols. Cloth. Price, \$3.50. Pp. 601, with illustrations. New York & London: Whittlessey House, McGraw-Hill Book Company, Inc., 1939.

The author has been secretary to the editor of the *Atlantic Monthly* and assistant to the business manager of Wellesley College. These two jobs ought to indicate that she herself is efficient. Her book offers a vast amount of advice to the girl who wants to rise in the profession of secretary and includes a discussion of important traits. Incidentally, she also discusses such detailed matters as the way in which the girl receiving dictation ought to sit, and she even discusses the executive who begins to dictate before the girl has time to sit. She mentions all the things that a secretary should ask the executive after he has finished his dictation so as to remind him of what he forgot. There are discussions of spelling, spacing, memorandums, telephone, handling of callers, making of files and appointments, and there is even a section on what the secretary is to do with her spare time, if any. The book has so much to say about so many little things which are significant in the life and work of a secretary that it is bound to be helpful to any secretary who has intelligence enough to be an efficient secretary in the first place.

Surgery of the Eye. By Meyer Wiener, M.D., Professor of Clinical Ophthalmology, Washington University School of Medicine, St. Louis, and Bennett Y. Alvis, M.D., Assistant Professor of Clinical Ophthalmology, Washington University School of Medicine, St. Louis. Cloth. Price, \$8.50. Pp. 445, with 396 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

For many years the American ophthalmologist has awaited a surgery of the eye which would not be a translation of a foreign textbook and which also would give in simple but descriptive words a practical treatise which could be used in everyday work. The authors of this small volume have achieved such an ideal. In addition the written technic has been combined with excellent drawings of the various stages in many operative procedures. This emphasis on clarity has made manifold the value of the book. Perhaps the most striking peculiarities of the text are the enunciation of surgical principles, the items of personal experience found inserted from time to time in all portions and the dogmatic statements of tried and proved methods which the authors have experienced in a long and busy surgical eye practice. In scope the authors have left little to be desired. Indeed no ophthalmologist in an English speaking country can afford to leave such a textbook off his "must" list.

Epidemic Encephalitis: Etiology, Epidemiology, Treatment. Third Report by the Matheson Commission. Willard C. Rappleye, Chairman. Fabrikoid. Price, \$3. Pp. 493. New York: Columbia University Press, 1939.

This is a complete contribution on epidemic encephalitis. It is the third report of the Matheson Commission and comprises etiology, epidemiology and treatment. It consists of five chapters: (1) the work of the commission; (2) summary of investigation on etiology of encephalitis due to epidemic, St. Louis type, Japanese B, equine encephalomyelitis, postvaccinal and postinfectious, hemorrhagic and Australian X-disease; (3) various allied diseases such as louping ill, lymphocytic choriomeningitis and the Guillain-Barré syndrome; (4) summary of the treatment of encephalitis with a description of about forty-eight methods of treatment; (5) epidemiology of epidemic encephalitis, St. Louis and Japanese B types of encephalitis. There is a comprehensive bibliography of about 3,510 papers on encephalitis. There is an excellent index. This book is recommended to all medical men as well as to bacteriologists, neurologists and pathologists.

Microbiology Applied to Nursing: A Combined Text Book and Laboratory Guide. By Jean Broadhurst, Ph.D., Professor of Bacteriology, Teachers College, Columbia University, New York, and Lella I. Given, R.N., M.S., Professor of Nursing Education, and Director, Department of Nursing Education, South Dakota State College. Fourth edition. Cloth. Price, \$3. Pp. 653, with 316 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1939.

The publication of this edition furnishes adequate recognition of the book's usefulness for the purpose for which it is designed. It is clearly written and well arranged to accompany the lectures and that small amount of laboratory work available to student nurses who must obtain some knowledge of the fundamentals of bacteriology.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Harrison Narcotic Act: Right of Florida Naturopaths to Registration.—The attorney general of Florida rendered an opinion to the effect that naturopaths may not prescribe or dispense narcotic drugs in the state. Basing his action on this opinion, the United States Collector of Internal Revenue for the District of Florida undertook to cancel naturopath Perry's registration under the Harrison Narcotic Act and to compel him to surrender the special narcotic stamp and order forms previously issued to him. The collector, too, refused to register naturopath Detwiler under the act. Each naturopath instituted suit against the collector in the United States district court, Florida, southern division, and the suits were consolidated for hearing.

The Harrison Narcotic Act provides that "physicians . . . and other practitioners, lawfully entitled to distribute, dispense, give away, or administer" narcotic drugs are entitled to register with the collector and receive from him a special stamp and order forms to be used in the purchase of narcotics. Who are physicians or other practitioners, the court pointed out, is to be determined by the law of the state where the applicant resides. The Florida narcotic act provides that the term "'physician' means a person authorized by law to practice medicine in this State and any other person authorized by law to treat sick and injured human beings in this State and to use, mix or otherwise prepare narcotic drugs in connection with such treatment." The Florida naturopathic act defines the word "naturopathy" to mean "the use and practice of psychological, mechanical and material health sciences to aid in purifying, cleansing and normalizing human tissues for the preservation or restoration of health according to the fundamental principles of anatomy, physiology and applied psychology, as may be required." Naturopathic practice, as recognized by the act, employs among other elements phytotherapy, which, the court said, means treatment by means or with the aid of plants or remedies of botanic origin. The naturopaths contended that phytotherapy embraces all botanic preparations and their compounds, including morphine, a derivation of opium, which in turn is a product of botanic origin, and that therefore they were authorized to prescribe and administer morphine and other narcotics of botanic origin.

The Florida naturopathic act, the court said, clearly does not recognize naturopaths as medical doctors, nor the practice of naturopathy as the practice of medicine. On the contrary, it authorizes licensees thereunder to practice the art of healing only in a limited and defined field called "naturopathy." That act, immediately after recognizing phytotherapy as a permissible method of treatment in naturopathy, continues with the following proviso: "Provided, however, that nothing in this Chapter shall be held or construed to authorize any naturopathic physician licensed hereunder to practice materia medica or surgery . . ." Literally, the court pointed out, materia means "medical material." To practice materia medica is to engage in that branch of medical science which deals with drugs, their sources, preparations and uses. The proviso is an express limitation on or qualification of the general authority of naturopaths as expressed in the general enacting clauses which precede the proviso. Though phytotherapy relates generally to healing with the aid of remedies of botanic origin, whatever is included in the practice of materia medica, that is, that branch of medical science which deals with drugs, their sources, preparations and uses, is expressly forbidden to naturopaths by the proviso. The act authorizes naturopaths to deal with botanic remedies contemplated by phytotherapy, exclusive of those embraced in materia medica. The situation is not altered by the fact that narcotics are used merely as a palliative to overcome pain rather than as a specific treatment for an ailment, the court said.

The Florida naturopathic act, while referring generally to phytotherapy as embraced within the practice of naturopaths,

does not, in prescribing a course of study for naturopaths, include botanic compounds or extracts generally, nor narcotics. This omission, the court thought, was in harmony with the restrictive proviso which prohibits the practice of materia medica by naturopaths. If naturopaths are to prescribe or dispense narcotic drugs in Florida, the court concluded, they must first secure legislative authority.

Judgment in each case was rendered for the defendant Collector of Internal Revenue. Naturopath Perry appealed to the United States circuit court of appeals, fifth circuit, which affirmed the judgment of the district court.—*Perry v. Larson, Collector of Internal Revenue; Detweiler v. Same*, 25 F. Supp. 728; *Perry v. Larson, Collector of Internal Revenue*, 104 F. (2d) 728.

Malpractice: Infection Following Hypodermic Injection of Morphine.—The plaintiff sued the defendant physicians, alleging that an infection in his arm was due to the negligence of the physicians' employees in administering morphine hypodermically. At the conclusion of the plaintiff's evidence, the trial court instructed a verdict for the physicians on the ground that the plaintiff offered no expert medical testimony that the infection in his arm was caused by anything done or omitted to be done by the physicians or their employees, and on the ground that there was no evidence showing a causal connection between the wrong complained of and the injury resulting. The plaintiff then appealed to the court of civil appeals of Texas, Austin.

In the case of *Floyd v. Michie*, 11 S. W. (2d) 657, said the court in the present case, it was held:

The law entertains in favor of a physician the presumption that he has discharged his full duty, and to defeat this presumption the law exacts affirmative proof of breach of duty coupled with affirmative proof that such breach of duty resulted in injury. Negligence is never imputed from results, nor is any inference thereof indulged in against a physician . . . To warrant the finding of civil malpractice there must be expert medical testimony to establish it and to establish the additional fact that death resulted from such malpractice. There being no expert medical testimony establishing such issues, the court properly instructed a verdict for the defendants.

In the present case, there was no testimony by a medical expert that the infection in the plaintiff's arm was caused by the hypodermic needle or that it resulted from negligent acts of the defendants.

What is an infection and whence it comes are matters determinable only by medical experts. As applied in the present case, infection, the court said, means internal inflammation where pus is formed by the presence of pus germs. Without medical testimony as to the probable cause of an infection or its source, the court and jury are not qualified to pass on the question. The mere fact that infection set up in the plaintiff's arm three or four days after a hypodermic needle had been injected will not suffice as proof of negligence in failing to sterilize the needle or skin of the plaintiff's arm before the injection. Infection comes from many sources, and there must be affirmative proof of such negligence or lack of care, and that the injuries complained of resulted therefrom. Such proof can be established only by the testimony of experts skilled in the medical and surgical profession.

The judgment of the trial court was affirmed.—*Kaster v. Woodson et al. (Texas)*, 123 S. W. (2d) 981.

Workmen's Compensation Acts: Melanocarcinoma Attributed to Constant Irritation of Mole.—The employee was engaged in the operation of machinery used in the manufacture of building blocks of sand, ashes and cement. Sand and ashes accumulated where he stood and some would get into his shoes, requiring him to empty them several times a day. On July 15, 1936, according to his testimony, he found at the end of the day's work on removing his sock that it stuck to a congenital mole on his left foot, that a tan colored stain was left on the mole where the sock had covered it and that there were sand and ashes around it. He testified that in the afternoon of that day he had felt pain at the site of the mole but that it did not bother him thereafter, except a "little bit," nor prevent his continuing at his work for several

weeks. About four weeks thereafter the mole started to "ooze," and he consulted a physician who advised him to go to a hospital. He did so two days later and remained there for three days, during which time the mole was cut out. Six weeks later he returned to the hospital and a further and more extensive operation was performed on his foot and leg. The attending physician diagnosed the condition as melanocarcinoma. The employee was denied compensation under the workmen's compensation act of New Jersey; the trial court affirmed that denial and the employee brought the judgment of the trial court for review before the supreme court of New Jersey. Subsequently the employee died, death being caused by the melanocarcinoma.

The employee's condition, in the opinion of the supreme court, was caused by the constant irritation of the mole by the sand and ashes with which it came in contact. It was not of accidental origin within the meaning of the workmen's compensation act but rather was an occupational disease for which no compensation was provided by the act. The first symptoms, the sticking of the sock to the mole and the stain on the mole, were not accompanied by any fall, blow or other trauma.

Because there was no accident that caused the disease or that caused a latent condition of the disease to flare up, the judgment of the trial court for the employer was affirmed.—*Bollinger v. Wagaraw Bldg. Supply Co. (N. J.)*, 3 A. (2d) 810.

Workmen's Compensation Acts: Refusal of Employee to Submit to Operation.—An employee, said the court of appeal of Louisiana, cannot under the provisions of the workmen's compensation act be required to submit to an operation to relieve a disability when the medical testimony shows that the operation will be accompanied by great pain and may seriously endanger life, or when there is doubt as to the removal of the disability by the operation. In such a case the employee is not required to endanger his life or gamble with his chance of recovery by submitting to a dangerous and uncertain operation. But when the medical testimony shows that the operation is a minor one, unattended by danger of any serious consequences, with little pain and suffering and with almost a certainty of success and relief from the disability, it would be unfair and inequitable for the employee to continue to draw full compensation when he had it within his power to minimize the damage by submitting to a minor and relatively simple operation.—*Leday v. Lake Charles Pipe & Supply Co. (La.)*, 185 So. 655.

COMING MEETINGS

- American Association for the Study of Neoplastic Diseases, Baltimore, Dec. 28-30. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue N.W., Washington, D. C., Secretary.
- American Society of Anesthetists, Los Angeles, Dec. 14. Dr. Paul M. Wood, 745 Fifth Ave., New York, Secretary.
- Annual Congress on Industrial Health, Chicago, Jan. 15-16. Dr. C. M. Peterson, 535 North Dearborn St., Chicago, Secretary.
- Eastern Section, American Laryngological, Rhinological and Otolological Society, Pittsburgh, Jan. 5. Dr. John R. Simpson, Medical Arts Bldg., Pittsburgh, Chairman.
- Middle Section, American Laryngological, Rhinological and Otolological Society, Kansas City, Mo., Jan. 19. Dr. Sam E. Roberts, Professional Bldg., Kansas City, Mo., Chairman.
- Radiological Society of North America, Atlanta, Ga., Dec. 11-15. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.
- Society for the Study of Asthma and Allied Conditions, Philadelphia, Dec. 9. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- Society of American Bacteriologists, New Haven, Conn., Dec. 28-30. Dr. I. L. Baldwin, Agricultural Hall, University of Wisconsin, Madison, Wis., Secretary.
- Southern Section, American Laryngological, Rhinological and Otolological Society, Columbia, S. C., Jan. 8-9. Dr. Walter J. Bristow, Doctors Bldg., Columbia, S. C., Chairman.
- Southern Surgical Association, Augusta, Ga., Dec. 5-7. Dr. E. Altan Ochsner, 1430 Tulane Ave., New Orleans, Secretary.
- Western Section, American Laryngological, Rhinological and Otolological Society, Los Angeles, Jan. 26-27. Dr. Pierre Viole, 1930 Wilshire Blvd., Los Angeles, Chairman.
- Western Surgical Association, Los Angeles, Dec. 15-16. Dr. Albert H. Montgomery, 122 South Michigan Blvd., Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

18: 261-388 (Sept.) 1939

- Factors Influencing Auricular Murmur and Intensity of the First Heart Sound. E. A. Stead Jr. and P. Kunkel, Boston.—p. 261.
Effect of Posture on Form of Precordial Leads of Electrocardiogram. H. J. Stewart and R. L. Bailey, New York.—p. 271.
Infra-Red Photographic Demonstration of Superficial Venous Pattern in Congenital Heart Disease with Cyanosis. B. S. Epstein, Brooklyn.—p. 282.
Plethysmographic Studies of Peripheral Blood Flow in Man: III. Effect of Smoking on Vascular Beds in Hand, Forearm and Foot. D. I. Abramson, Cincinnati; H. Zazecia and B. S. Oppenheimer, New York.—p. 290.
*Heart Sounds in Young Adults. H. A. Sacks and R. C. Roberts, Chicago.—p. 303.
Significance of Duration of Q_s with Respect to Coronary Disease. R. H. Bayley, New Orleans.—p. 308.
Treatment of Occlusive Arterial Disease of Legs by Means of Sanders Vasocillator (Sanders Bed). N. W. Barker and Grace M. Roth, Rochester, Minn.—p. 312.
Syndrome of Superior Vena Caval Obstruction. L. A. Soloff, Philadelphia.—p. 318.
Cold Pressor Reaction in Normal Subjects and in Patients with Primary (Essential) and Secondary (Renal) Hypertension. J. H. Miller and M. Bruger, New York.—p. 329.
Clinical Significance of Right Axis Deviation in Electrocardiogram. W. J. Comeau and P. D. White, Boston.—p. 334.
Precordial Electrocardiogram in Myocardial Infarction: II. Observations on Cases of Infarction of Posterior Wall of Left Ventricle. C. E. Kossmann and C. E. de la Chapelle, New York.—p. 344.
Id.: III. Observations on Cases in Which Lesions Were Diffuse. C. E. Kossmann and C. E. de la Chapelle, New York.—p. 352.
Method for Study of Ventricular Fibrillation. B. Blumenthal and Enid Tribe Oppenheimer, New York.—p. 363.

Heart Sounds in Young Adults.—Sacks and Roberts used the stethograph in determining the characteristics and time relationships of the heart sounds of 110 normal young adults (medical students) and the significance of systolic and diastolic vibrations, exclusive of the heart sounds themselves, occurring in the absence of audible murmurs. All records examined revealed a normal sinus rhythm, with the heart rate varying from 60 to 90 beats a minute. Sixty-eight records (61.8 per cent) showed vibrations during systole. These varied in number from four to twenty-six. Systolic murmurs were audible in ten instances (9 per cent) and examination of the stethograms of these subjects revealed that from sixteen to twenty-six systolic vibrations were present in every record. In the other fifty-eight cases in which there were systolic vibrations and no audible murmur, only twelve records resembled those obtained from the subjects with audible systolic murmurs. The inaudible systolic vibrations occurred more often in the asthenic type of individual. Early diastolic vibrations were present in fourteen cases (12.7 per cent). The maximal number of vibrations recorded was from eight to ten. In no instance was a diastolic murmur audible through the stethophones. The systolic vibrations found in the normal subjects with records of organic murmurs were compared with those found in fifty cases of organic heart disease in which there were obvious systolic and diastolic murmurs. In the majority of the cardiac cases an organic systolic or diastolic murmur was represented by from sixteen to forty-four vibrations. Thus it became clear that 20 per cent of the total normal group had from sixteen to twenty-six systolic vibrations that could not definitely be distinguished from the recorded murmurs of organic heart disease. However, the well defined organic murmurs usually had more vibrations and were of longer duration. The results suggest that, in the interpretation of stethographic records, systolic vibrations should not be regarded as actual murmurs unless there are at least sixteen regular oscillations. A few irregular oscillations in systole or diastole may be due to the impact of the apex against the wall of the chest or to other extracardiac factors.

Risk of Metastasis from Biopsy.—Paterson and Nuttall compared the incidence of metastases in patients with similar lesions but divided into two groups, in one of which biopsy was performed and in the other it was not. A number of conditions had to be met, which limited the choice of cases suitable for analysis. A type of tumor which habitually metastasized in a readily recognizable way was essential in order that the patients might be followed up in a routine clinical manner without requiring special examinations at each visit. The patients chosen suffered from malignant disease of the skin, mouth, lips and penis. The biopsy group included only squamous cell carcinoma. The study thus became one on the risk of biopsy in squamous carcinoma rather than a general study of biopsy risks. Early lesions of suitable type with no involvement of lymph nodes undergoing treatment by radium molds were alternately sectioned and not sectioned before application of the mold. The time between treatment and analysis varied between one and a half and four and a half years. Such an interval was considered to be long enough for metastases to appear if they were going to occur, though occasionally much greater intervals have been recorded. At the end of two years 202 cases had been listed. Thirty-six did not fulfil all the criteria. Of the remaining 166 cases, biopsies were done in ninety-nine and they were not done in sixty-seven cases. Of the group in which biopsy was done metastases developed in 19 per cent as compared with 20.5 per cent in the group without biopsy. This discrepancy is well within the limits of casual error of a limited sample. The number of patients less than 45 years of age is small, but it is interesting that no metastases occurred in this group. The incidence in the other two age groups (from 45 to 65 and more than 65) is reasonably equal. The fact that the percentages were fairly constant in all the subgroups the authors believe is an additional indication that the figures are representative and not accidental. The purity of the samples and the fact that the higher figure for metastases occurs in the group without biopsy provide substantial evidence against the belief that biopsy causes metastasis in any appreciable percentage of these (squamous carcinoma) cases.

Encephalitis Viruses in California.—Howitt reports that during the summer and autumn of 1937 physicians in California reported a number of cases of acute encephalitis, in some of which the course was stormy and in others less violent. There

were forty deaths. Most of the cases occurred in Fresno and Tulare counties. During the same seasonal period in 1938 a similar type of disease was recorded showing both the severe and the milder forms. Fresno and Tulare were again affected, with additional patients from Kern County. The western strain of the equine virus was recovered from the brain and the blood, respectively, in two cases. Both strains were shown to be immunologically and serologically similar to the virus of equine origin. Positive neutralization to the St. Louis virus was obtained in forty-nine (47.5 per cent) of 103 serums and positive neutralization to the equine virus (Br) in thirty-two (37 per cent) of eighty-six serums. Of a total of sixty-three apparently normal persons, contacts and noncontacts, residing in both the Bay Region and the San Joaquin Valley districts, eight had neutralizing substances for the St. Louis virus and one for the equine. With the exception of one for the St. Louis type, all of the group with positive reactions resided in the valley. Of a total of forty-seven persons tested for equine virus and sixty tested for the St. Louis strain among groups with a condition diagnosed as poliomyelitis in both regions, the only subjects with serums positive for either virus were residing in the San Joaquin Valley. Fourteen of twenty-one serums positive to the Br equine strain also gave strongly positive neutralization with the western virus of equine origin (Californian), while four were weakly positive. Neutralizing antibodies for the Br equine virus could be obtained as early as eight days after onset of the disease and were found in some persons one, two and even three years after recovery. The predominance of positive reactions for the St. Louis virus was among the older people, while that for the equine was among the younger. No definite relationship was noted between cases of the equine disease in horses and those in man. Swampy lands and many mosquitoes were closely associated with the districts affected. From the epidemiologic evidence it seems likely that the equine virus was transmitted to man through some vector. The St. Louis strain was brought in by the migrant labor population.

Active Immunization Against Diphtheria.—In a test survey for determining the efficacy of several methods of active immunization against diphtheria Harder and his associates compare the artificial and the natural immunity (as measured by the Schick test) of 544 noninoculated children, 208 receiving four injections of toxin-antitoxin, 735 given three injections of toxin-antitoxin, 650 given two injections of Ramon toxoid and 219 given one injection of alum-precipitated toxoid. The observations in the various groups were not exactly comparable because the intervals of time between administration of the various antigens and testing were not always the same. Nevertheless, it was possible to reach certain conclusions. Each of the groups of inoculated children showed a definitely higher level of immunity than the control group. This was particularly significant because the controls were older and therefore had a higher level of natural immunity. The relatively good results in the group that received one injection of alum-precipitated toxoid may have been due to the short interval of time between inoculation and testing (one year or less). The somewhat poorer results in the group given two injections of Ramon toxoid may have been due to the younger age of the members of this group or to the fact that they received only two injections one week apart. The results in the group which received toxin-antitoxin were relatively final and represented the resultant immunity status after primary stimulus and natural immunization had reacted over a substantial period of years (four to six). There was no significant difference between the immunity levels of those who received three and those who received four injections of toxin-antitoxin. The authors conclude that no actively immunizing agent provides perfect protection against diphtheria. This is not surprising as the disease itself does not provide complete protection against subsequent attacks. Diphtheria affects predominantly poor white children. In the control of the disease, the improvement of living and housing conditions is important.

Atmospheric Lead from Colored Blackboard Crayons.—Ruf and Fluck state that the Wisconsin State Board of Health was recently requested to analyze two samples of yellow blackboard crayons suspected of containing lead. The analysis showed they contained respectively 7 and 8.8 per cent lead. Subsequent discussions with school officials disclosed that yellow

blackboard crayons were used extensively, especially in defective vision classes. The possibility of lead poisoning due to inhalation of lead dust during use of some of the colored crayons was investigated. Twenty-seven crayons obtained from six manufacturers were analyzed for their lead content. The crayons were obtained from various schools or school supply houses in Wisconsin without selection. In studies relative to the amount of crayon dust dispersed into the atmosphere under controlled and actual classroom conditions, atmospheric samples were collected at the breathing zone of the person writing and in the center of the room at a height corresponding to the breathing level of students. Data show that with use of 6.8 per cent lead crayons under controlled conditions, the concentration of lead in the air may at times exceed the 1.5 mg. of lead per ten cubic meters of air recommended by the United States Public Health Service as the maximal amount permissible for prolonged exposure. During a writing period of thirty minutes the amount of lead at the breathing zone of the person writing is dependent on the rate of crayon usage. During the writing period the lead was dispersed throughout the room air, but in all cases the concentration was below that at the blackboard. The maximal concentration of lead found in samples of air collected seventy minutes after writing ceased was 0.2 mg. per ten cubic meters of air. The results under classroom conditions agree with those of the controlled group in that ordinarily the concentration of lead in the air at the center of the room was below 1.5 mg. per ten cubic meters of air. However, under adverse conditions (when much crayon is being used or many students are writing) it seems reasonable to expect that higher concentrations of lead may occur. During one test, in which 13 Gm. of crayon was used in one hour's writing, the concentration of lead in the air at the blackboard was 5.9 mg. per ten cubic meters. Persons subjected to the greatest lead exposure are teachers and students writing at the boards and janitors cleaning boards, erasers and classrooms. As children appear more susceptible to lead intoxication than adults, the desirability of replacing lead chromate as a pigment is apparent. In addition to absorption of lead by inhalation, the danger of ingestion by nibbling pieces of crayon should not be ignored. The fact that at least one manufacturer has produced a yellow crayon free of lead shows that the hazard can be eliminated.

Lymphosarcoma of Stomach.—Archer and Cooper sent a questionnaire to all diplomates of the American Board of Radiology and asked that they cite all microscopically proved but heretofore unreported cases of these tumors. The information gleaned from this questionnaire reveals ninety-one cases and the authors add three of their own. In these ninety-four cases thirteen five year cures have been disclosed. In eight irradiation alone was used, in one only surgery and in four both surgery and irradiation. No single symptom or x-ray sign is pathognomonic of the growth, the diagnosis being practically impossible except possibly at operation, when a softer tumor than the usual carcinoma is felt. A frozen section will then be quite helpful. Enlarged rugae are not believed to play a

prominent part in x-ray diagnosis. Acid values may or may not be decreased. Healing of an ulcer does not eliminate the possibility of sarcoma.

Röntgen Therapy for Venereal Lymphogranuloma.—Martin and de Lorimier used roentgen therapy in sixty-one cases of venereal lymphogranuloma. Only one of the patients was a woman. In all but four the active processes concerned inguinal glands. In one of the four the involvement appeared primarily to have existed on the tongue and mucous membranes of the cheek and oral pharynx. The other three extragenital lesions were manifested by constrictions in the lower colon or rectum. Frei reactions were positive in forty-two of the patients. Twenty of these admitted that they had had some type of primary lesion and in most instances these were described as small ulcerations. The descriptions by the patient whose mouth and oral pharynx were involved indicated that herpetiform lesions had recurred at irregular intervals for about two years. The losses of roentgen radiation required varied. To avoid marked reactions the authors started treatment with as little as 50 roentgens. In cases showing little evidence of swelling or inflammation, 100 roentgens was given. When 50 or 100 roentgens was given, the interval between treatments was one week. When the dosage was increased to 200 roentgens the interval was increased to two weeks. Later, when 300 roentgens was applied the interval was increased to three weeks. In a few cases as much as 400 roentgens was given but the interval between treatment was never extended beyond three weeks. Roentgen irradiation was continued at intervals of from one to three weeks until the activity of the lesions subsided. Patients were not incapacitated for more than the first few weeks. Thereafter they were able to carry on their usual work. In approximately 60 per cent of the cases fistulous tracts developed either spontaneously or as a result of incisions made by the referring physician. In both instances, drainage stubbornly continued. The presence of the fistulous tracts seemed to add to the indications for roentgen therapy. The quality of roentgen rays varied somewhat. In attacking the inguinal adenitis a kilovoltage of 140 was used. The filtration was of the equivalence of 0.30 mm. of aluminum, the half-value layer being obtained with 0.30 mm. of copper—a wavelength equivalence of 0.205 angstrom. The four extragenital cases were treated with a shorter ray. The portals of irradiation were reduced to a minimum. All treatments were given with the use of a cone whereby the focal skin distance was 37 cm. Unfavorable developments occurred in only two of the fifty-seven cases involving the inguinal glands. There have been no known recurrences of activity among the patients. The authors believe that venereal lymphogranuloma should be considered in cases of inguinal adenopathy, especially when the involvement is predominantly unilateral and when there is matting and tenderness of the glands. The presence of an ulcer about the genitalia should not designate the case as one of syphilis or Ducrey infection, though the possibilities must be considered. The development of multiple fistulous tracts from lymphatic glands should lead one to consider venereal lymphogranuloma. Smears and cutaneous tests should be made, as well as repeated serologic examinations. The Kahn test was positive in eight of the sixty-one cases. This condition should also be considered in cases of stubborn chronic granulomatous lesions in the mouth or oral pharynx, especially if such cases manifest a marked regional lymphadenitis and a tendency toward persistent formation of fistulous tracts. It should be considered in cases of annular or bandlike constrictions in the colon or rectum. Irradiation must be applied at intervals, protracted over a period of from one to three months. The glands as well as the sinus tracts should be irradiated.

Röntgen Treatment of Lobar Pneumonia.—Solis-Cohen and Levine irradiated twenty lobar pneumonia patients and found that if adults were treated in the department before the fourth day of the onset of the disease they recovered without complications. Adults treated at the bedside required more frequent treatments, and many more complications developed. Adults treated after the fourth day either with high voltage or at the bedside had a more severe course. The favorable syndrome (decreased fever, a feeling of comfort and an initial fall in leukocytosis) was experienced by all patients who recovered but not by the patients who died. Four adults died, two of

whom were hopelessly ill prior to irradiation, and the corrected mortality is therefore 10 per cent. One of the twenty-two children irradiated died; bacteremia and a mastoiditis developed in this child. The course of the disease was more severe in children and adults who were not irradiated. In four irradiated adults the disease was practically aborted and crisis or lysis exhibited a tendency to occur earlier than in the nonirradiated patients. Oxygen tents were less often necessary for the irradiated patients. In the forty adults who received no irradiation, seven were treated with serum; two of these died, together with eight who did not receive serum. The death rate was 25 per cent. Fifteen of the recovered patients had a stormy course and there were major or minor complications in twenty of the series. Nine of the twenty adult patients received from 150 to 200 roentgens and eleven from 300 to 400 roentgens. Of the children, fifteen received from 200 to 300 roentgens and seven 150 roentgens. The death rate in the children given roentgen therapy was not influenced, as one of twenty-one nonirradiated children died; but the irradiated children were comfortable, complications did not develop and they passed through a less stormy course.

Obstructive Origin of Appendicitis.—Wangersteen and Dennis present evidence of the secretory capacity of the vermiform appendix of man. The behavior of the appendix when obstructed temporarily is described, and factual proof of the reproduction of the pathologic picture of spontaneous appendicitis through the agency of obstruction is presented. In a patient presenting a carcinoma of the ascending colon, it was possible to exteriorize the greater portion of the right half of the colon and the terminal ileum. A few days later, when the exteriorized intestine had become fairly well covered with fibrin and effectual sealing of the wound had occurred, the base of the appendix was ligated securely. The attachment of a closed water system connected to a recording manometer permitted determination of the ensuing increase in intraluminal pressure. When preliminary colostomy was being performed for a malignant condition of the large intestine or rectum prior to excision of the lesion, the appendix was exteriorized and obstructed. The

secretory activity of the obstructed appendixes is summarized. The highest recorded pressure was 126 cm. of water. This level was reached twenty-two hours after exteriorization and obstruction of the appendix of a man 68 years of age. No secretory pressure developed in three of the twenty-two exteriorized obstructed appendixes. In six other instances a secretory pressure of less than 20 cm. of water was recorded. In nine instances the highest secretory pressure exceeded 40 cm. of water; in seven of these the pressure was sustained above 85 cm. In four instances, pressures intermediate between 20 and 40 cm. of water attended obstruction of the exteriorized appendix. These data the authors believe support the thesis that in the vermiform appendix of man, when obstructed, a secretory pressure will develop in the majority of instances which will threaten the viability of the appendical wall. However, there are instances in which no evidence of secretory pressure attends luminal obstruction. Such appendixes undoubtedly would tolerate luminal obstruction without hazard. It appears likely that the chief inciting agency in bringing about appendicitis in man is obstruction of an appendix in which the mucosa (not atrophic) possesses the normal secretory capacity.

Liver Trauma and Hepatorenal Syndrome.—Orr and Helwig report five cases of hepatic injury associated with renal damage in all of which some degree of a toxic effect on the kidneys was shown by an increase in the blood of nonprotein nitrogen and creatinine and in the urine of albumin, pus and casts. In two cases there was postmortem examination. The changes in the blood and urine occur rapidly after severe hepatic injury. In less than twenty-four hours there was retention of nitrogen, and albumin, casts and frequently pus and erythrocytes were present in the urine. Helwig and Schutz observed these rapid changes in the blood and urine of dogs dying within twelve hours after the liver was traumatized. It is difficult to believe that infection is a factor in the hepatic and renal changes. The three patients operated on all had infected wounds, but the changes in the blood and urine were present before the infection developed. In case 2, general peritonitis was found at necropsy but the blood chemistry had returned to normal before death. It is believed that in this patient death was not directly due to the toxic effect of the hepatic trauma but was caused by the complicating infection. In case 1, the blood returned to normal although a severely infected wound and later an empyema developed, from which the patient recovered. Krieg has presented evidence which pointed to a toxic condition on an uninfected basis. From the clinician's standpoint the practical value of the observations on blood and urine incident to hepatic trauma are worthy of consideration. Although the nitrogen retention in the blood develops early after hepatic damage, the importance of early operation to control hemorrhage would negate the value of the changes in the blood and urine as a diagnostic aid in many cases. However, in those cases in which bleeding is slow and the condition of the patient warrants a delay of a few hours to establish the diagnosis of hepatic injury, the changes in the blood and urine may be of some diagnostic value. In case 2, operation was delayed for twenty-four hours, during which time the nonprotein nitrogen rose to 131 mg. and the creatinine to 4.1 per hundred cubic centimeters of blood. This patient had other injuries complicating the picture, but knowing that such blood changes are associated with hepatic damage aided in confirming the diagnosis of rupture of this organ. Frequent estimations of the nonprotein nitrogen and creatinine may be of definite value in the prognosis. Certainly an increase in nitrogen retention indicates an increase in toxicity. Delirium may be an outstanding symptom; it was observed in four of the cases reported. After a few days there develops a hemorrhagic tendency, similar to that observed in patients with jaundice. The treatment of severe hepatic trauma is the treatment of shock plus operation to control bleeding and administration of dextrose to maintain liver glycogen and promote diuresis. The quantity of sodium chloride given must depend to some extent on the quantity lost by vomiting. Usually the administration of chlorides is not an important factor in treatment.

Blood Cholesterol and Gallbladder Operations.—Pickhardt and his co-workers state that in normal persons the ratio of esterified to free cholesterol is a physiologic constant. Any alteration in this relationship indicates a disturbance in the ability of the liver to regulate the synthesis and hydrolysis of

cholesterol esters. They believe that the liver has a functional reserve, which is reflected by changes in the cholesterol partition. A rise in the percentage of free cholesterol of the blood serum is indicative of a lowering of the functional reserve. They show that changes in the cholesterol partition are of clinical value in determining the functional reserve of the liver in hepatic disturbances associated with surgical therapy of the biliary tract and thus serve to indicate the optimal time for a planned surgical intervention. A patient who exhibits a low functional reserve of the liver is a poor operative risk. Medical treatment should be instituted, and repeated estimations of the cholesterol partition will indicate when the functional reserve has returned to normal. The cholesterol partition has prognostic value in surgical treatment of the gallbladder and biliary tract. The cholesterol partition of the blood serum should be determined both preoperatively and postoperatively for all patients with biliary disease and jaundice.

Angina Pectoris in Hereditary Xanthomatosis.—Hereditary heart disease due to xanthomatosis is fairly common. Müller believes that he has demonstrated it as a dominant factor in seventeen families, with seventy-six individuals affected. He divides the affected persons into three familial groups: the families in which xanthoma tuberosum and eventually palpebral xanthelasma occurred; the families with palpebral xanthelasma, and the families in which there were no changes in the skin or subcutaneous tissue but in which the cardiovascular disease occurred in combination with hypercholesterolemia and in which postmortem observations or other factors suggested that xanthomatosis might be the main cause of the cardiovascular disease. The group consists of forty-four women and thirty-two men from 31 to 85 years of age, the average for the living members being 56.3 and for the deceased ones 60.9 years. Most of these persons were office workers or teachers. The laboring class was not represented. Of the seventy-six persons, sixty-eight appeared to have had heart disease, while eight had xanthelasma only. Of the sixty-eight persons, the diagnosis of angina pectoris seemed indicated in fifty-nine, of whom thirty-eight have died, fourteen suddenly. Of the seventeen family histories, in eight xanthoma tuberosum was encountered alone or combined with xanthelasma, in six there were records of xanthelasma only and in three there were no records of cutaneous changes. Cutaneous xanthomatosis in one form or another occurred in thirty-eight persons, xanthoma tuberosum in twenty-four and xanthelasma in fourteen; ten had the two forms at the same time. The quantity of cholesterol in the blood was estimated for thirty-seven patients; the amount varied from 129 to 560 mg. per hundred cubic centimeters. The reports presented confirm the previous observations on xanthomatosis as a cause of heredi-

tary heart disease. They reveal further that the syndrome of cutaneous xanthomatosis, hypercholesteremia and angina pectoris presents itself as a well defined clinical disease entity in the first, second, third and fourth generations, that is, as a dominant hereditary disease. There can be hardly any doubt but that xanthomatous deposits in the coronary artery and consecutive myocardial ischemia are the cause of the angina pectoris. The disease may cause changes in the mitral and aortic valves. The form of angina pectoris under discussion may occur in patients without external xanthomatosis. Data on two families illustrate that xanthomatosis may occur in a few members or only one member of a family, while relatives have heart disease and hypercholesteremia. In xanthomatosis, angina pectoris not only may occur at an early age with sudden death but more often appears as typical angina pectoris, lasting for years in middle-aged as well as in old persons; that is, it appears at the time that this disease usually occurs, from the sixtieth to the seventieth year or even later. In sixteen cases in the present series it commenced before the fiftieth year and in eight of these between the thirty-first and the fortieth year. Symptomatically this form of angina pectoris does not differ from the usual form. Xanthomatous cardiac lesions probably develop in persons who have no evidence of xanthomatosis in the skin. Xanthoma tuberosum and xanthelasma may be overlooked in clinical examinations and may be confused with other cutaneous conditions. The occurrence of heart disease in families should direct the attention to xanthomatosis, especially when rheumatic fever, syphilis and hypertension do not appear to play any part. Treatment of the cardiac symptoms in xanthomatosis does not differ from that of cardiac symptoms under other conditions. The patients are benefited by quiet, rest in bed and nitrites. A diet poor in cholesterol may be of prophylactic value to persons with a hereditary predisposition.

Climatic Factor in Mastoiditis.—During 1938, ninety-two mastoidectomies were performed on children by the attending otologic staff of a pediatric hospital. Fabricant selected five cases from this group to illustrate the influence on the clinical course of the ailment of daily meteorologic and seasonal changes. Simplified meteorographs have been prepared from the United States government meteorologic data; for purposes of simplification the high and low range of daily temperature were regarded as an adequate index of meteorologic change. From the data obtained Fabricant concludes that mastoiditis is most often precipitated in the wake of a fall in atmospheric temperature (cold front or polar front), when the functional status of the mucous membranes of the nose and throat has changed.

Sulfanilamide Therapy for Otogenous Infections.—Because of its tendency to obscure the clinical course of the infection, Maybaum and his associates believe that sulfanilamide should be used cautiously if at all in acute otitis media. It is contraindicated during the course of suspected mastoiditis before operation and also after operation unless meningitis, sinus thrombosis or cerebral abscess complicates the disease. For the present, at least, they believe that the indications for its use are as follows: Sulfanilamide may be given in otitis media before suppuration sets in. However, otitis media of

this type commonly proceeds to spontaneous resolution. Occasionally, in cases of extreme bacterial meningitis (streptococci or pneumococci), intensive administration is indicated before operation (twenty-four to thirty-six hours) and then postoperatively. Sulfanilamide should be given in sympathetic meningitis secondary to an extradural abscess, an abscess of the brain or labyrinthitis. In thrombosis of the lateral sinus sulfanilamide should be followed by thorough surgical intervention and continued postoperatively. The drug is especially useful in instances of continued otitic sepsis, even though a thorough operative procedure has been previously performed. In petrositis sulfanilamide should not be administered during the period of observation because of the danger of masking the clinical course and thus interfering with the proper management of the condition. If operation is indicated sulfanilamide should be given promptly in the usual manner. Indiscriminate use of sulfanilamide may result in latent forms of infection of the middle ear or the mastoid and their complications. That sulfanilamide tends to mask the clinical picture of otitic infection has been observed often. A striking example of latency due to the administration of sulfanilamide was recently reported by Smith and Coon, who stated that a moderate dose of sulfanilamide may partially control meningitis so that it presents an unfamiliar clinical picture.

Insulin for Toxic Hallucinoses.—On the basis of Sakel's explanation for the use of insulin in the treatment of morphine addiction, that is, "that insulin abolishes the phenomena of irritation during abstinence from morphine, because the nerve cells were blocked, and their function quantitatively affected," McAdoo and Prout began using insulin in eight cases of alcoholism associated with abnormal mental phenomena, particularly with hallucinoses. The subjects were selected from the consecutively admitted patients who presented evidence of hallucinatory phenomena of persistent nature which followed overindulgence in alcohol or which made their appearance after the withdrawal of alcohol. The hallucinations were, in most cases, both auditory and visual. The size of the dose of insulin varied from a minimum of 10 to a maximum of 25 units. The reaction (hypoglycemia) to dosage has been found to be extremely variable. A nursing personnel trained in the observation of patients receiving insulin therapy is absolutely essential. The repetition of dosage has been largely dependent on the needs of the individual, with a maximal frequency of every two and three-fourths hours. The largest number of treatments required was eleven, for a total dosage of 95 units, although 135 units were given in a smaller number of doses to another patient. The treatment was most satisfactory when it was continued for at least twenty-four hours after the hallucinations disappeared. The effect of the injections was largely sedative, with definitely and progressively decreasing evidence of severity in the reaction of the patient to the hallucinations. The most striking observation is that during the hospital residence the average total duration of the hallucinations in the treated series (143.6 hours) is definitely less than that in the untreated series (306 hours). On subtracting the average number of hours of active hallucinoses in the hospital prior to treatment with insulin from the total hours of hallucinoses in the hospital in the untreated series a still greater and even more striking contrast is obtained. The average figure for continued hallucinations following the institution of insulin therapy in the treated series was 50.4 hours,

as compared with 115 hours in Piker and Cohn's series of cases in which they used spinal puncture, dextrose and paraldehyde, and with 79.2 hours for untreated patients and 31.2 hospital hours for patients treated with insulin cited by Robinson.

Tuberculosis After 45 in Indiana.—According to Jennings, a general impression held by the medical profession and the laity is that tuberculosis among older people is almost non-existent. While it is true that a greater number of persons less than 45 years of age die of tuberculosis the difference is not so great that this erroneous idea is justified. Although there has been a definite decrease in the total number of deaths from tuberculosis in persons more than 45 years of age, further analysis of these figures shows that the proportion in this age group when considered in relation to the total number of deaths for all ages has not decreased; in fact, there has been a slight increase. In the state of Indiana there has been a gradual increase in this percentage. In 1938, 45.2 per cent of all the tuberculosis deaths in the state occurred in persons in this age group. In 1933 and again in 1938, 50 per cent of all the male tuberculosis deaths occurred in men 45 or more years of age. The percentage increase in deaths due to tuberculosis has exceeded the percentage increase in population of persons more than 45 years of age. Persons in this age group undoubtedly act as potential spreaders of the tubercle bacilli.

Transient Paralysis from Postural Hypotension.—Thomas reports the case of a 65 year old man who has had innumerable attacks of transient paralysis of the right arm and leg and occasional blurring of vision of the left eye. These symptoms were reproduced by raising the patient on a tilting table from the flat to a 75 degree erect posture, at which time his blood pressure fell momentarily from 130 mm. of mercury systolic and 88 diastolic to 82 systolic and 55 diastolic or even lower. The paralysis passed in five or ten minutes with absolutely no residuum. The author believes that this apoplexy is caused by a fleeting localized cerebral ischemia which occurs in the course of a decrease in blood pressure from postural hypotension. The degree of narrowing of the lumen from arteriosclerosis of the various cerebral vessels determines the point at which the ischemia first produces symptoms. So sudden

is the paralysis in the leg that the patient falls to the ground if he is not clinging to a chair or some other object for support. Stimulation of a hypersensitive carotid sinus may cause a sudden lowering of the blood pressure, but it is suggested that in this patient the postural hypotension is associated with an insensitve reflex pressor mechanism rather than with a hypersensitive reflex depressor mechanism. The occurrence of transient dimness of vision in one eye may be explained by the calcified bodies observed in a roentgenogram of the region of the internal carotid artery, which strongly suggest advanced sclerosis of this vessel. The physiologic explanation has served in this case as a basis for treatment. Treatment designed to prevent excessive drops in blood pressure has greatly diminished the number and severity of the attacks.

Standards of Immunization Against Diphtheria.—This report, Rosenberg explains, expresses the conclusions of the Committee on Child Health regarding a standard uniform method which a family doctor can follow in immunizing children against diphtheria. Health officials advocate immunization of children at about 9 months of age, followed by Schick retesting on their entering school, and the administration of another cycle of immunizing injections to children who have lost their immunity. This is probably the most logical plan. This procedure would be similar to that adopted in various European countries in infancy and a second on entering school. While the last word on the subject has not yet been written, the following procedure, in the opinion of various health officers, is recommended: to use the plain toxoid as the material of choice; to give a minimum of two injections, although three are preferable; to begin the injections at about the age of 9 months; to check this immunity four months later by a Schick test; to retest the children on entering school as to the persistence of their immunity, and to reinoculate the children found to have lost their protection.

Dextrose Tolerance Test in Recurrent Infectious Intertrigo.—Carpenter suggests that the carbohydrate metabolism should be determined in any person who has a chronic relapsing form of intertrigo so that if there is any defect it will be known. A simple test for blood sugar is not sufficient, for it may be within normal bounds. Campbell, in studying sugar metabolism of patients with pruritus, outlined a form of dextrose tolerance test which would indicate an abnormally delayed assimilation of carbohydrates. He gave orally 100 Gm. of dextrose on an empty stomach, and then took blood sugar readings one-half, one, two and two and a half hours after its administration. If the average result of these tests is more than 120 mg. per hundred cubic centimeters, he considers that an abnormal delay is present and that carbohydrate dietary restrictions should be enforced. In addition, in a few selected cases insulin may be necessary, in low dosages, until the acute manifestations are under control. No rational plan can be laid out for local treatment, but persistence and patience are indispensable.

Bulgarian Belladonna for Chronic Encephalitis.—Neal used a white wine extract of the root of Bulgarian belladonna or tablets prepared from this extract in the treatment of seventy-five patients with chronic encephalitis; in most instances they

found to be acutely inflamed (nine cases). The correlation of appendicitis with infections of the respiratory tract was attempted but was not demonstrated. Oxyuris vermicularis infestation as a cause of acute inflammation was infrequent, but there appeared to be a clinical syndrome indistinguishable, with safety, from appendicitis produced by such infestation. There was no definite evidence that fecaliths initiate acute appendical inflammations. The symptoms, signs and changes in the peripheral blood were sufficiently consistent to make diagnosis before perforation possible even in the very young. The triad of abdominal pain, vomiting and slight fever must be considered presumptive evidence of acute appendicitis, and frequent, gentle and painstaking examinations should be made during the first twelve hours of illness to corroborate or disprove such a diagnosis. The general policy, with but few exceptions, has been immediate operation irrespective of the type of appendicitis. Operation was delayed only when parenteral fluids were indicated. Primary appendectomy was performed in 95 per cent of the cases. A rectus-retracting or muscle-splitting incision was generally used. A drain or drains were introduced in the presence of peritonitis and often in the presence of fluid not definitely purulent. Duodenal drainage, parenteral administration of fluid and morphine were used liberally. A high oxygen atmosphere was maintained in the presence of distention. Fowler's position and the application of heat to the abdominal wall were employed in the majority of cases. The mortality rate was 3.06 per cent (twenty-six deaths in 848 cases). The authors believe that the factors affecting the mortality rate were, in the order of their importance, (1) the type of appendicitis present at the time of admission, which in turn is governed by the duration of the attack before diagnosis and the age of the patient, (2) the treatment employed, (3) coexistent disease and (4) the age of the patient. There need be no inherently high mortality rate based on age alone provided that a diagnosis is made comparatively early and the young patient is treated wisely. Figures are presented which demonstrate the continued need for lay education and, to a lesser extent, for reemphasizing the problem to the medical profession.

had been in that stage for ten years or more. Different lots of the extract average about 2.3 decimilligrams of total alkaloids per cubic centimeter and the tablets from 3.1 to 3.5 decimilligrams. In two or three cases there was a question as to whether the parkinsonism was on an arteriosclerotic or encephalitic basis, and in two there was an outstanding psychogenic factor. The patients continued to live in the same environment and under the same conditions as they previously had. They took no other drugs. No special diet was advised. It was recommended that they abstain from alcoholic beverages. The patients were usually started on a dose of 2 cc. of the decoction, or one tablet, taken just before retiring. This dose was increased daily by 1 cc. of the decoction or by one tablet until there was rather marked dryness of the mouth or blurring of vision. None of the patients showed mental confusion. The optimal dose varied between a minimum of from 4 to 8 cc. of the decoction (or the equivalent of the alkaloidal content in tablet form) and a maximum of from 30 to 50 cc. Some patients prefer taking the entire dose just before retiring; others prefer to take the total dose in divided portions. It is most important that these patients be under close medical supervision until the optimal dose is established and under frequent medical observation thereafter. In general, the decoction and the tablets were equally effective. Of the seventy-five patients 22.67 per cent were slightly improved, 48 per cent were moderately improved and 29.33 per cent were greatly improved. Practically all of the patients showed subjective improvement. They felt stronger, were less drowsy during the daytime and rested better at night; they were less tense, more cheerful and less given to fits of depression. Objectively, there was some relaxation of the muscular rigidity. This was shown in an improved facial expression, greater ease in rising from a sitting position, a more normal gait and improvement in speech. In practically all cases salivation was entirely relieved. The profuse perspiration from which a few patients suffered was also definitely diminished. While oculogyric crises usually became less frequent, less severe and shorter in duration, in no instance in the group have they been abolished completely. One case of narcolepsy following encephalitis, of many years' duration, has been improved in a short time, although the results with ephedrine and benzedrine were unsatisfactory.

Hematemesis and Perforation.—Davies and Wilson call attention to the nervous influences which in certain personality types seemingly play a part in precipitating hematemesis and perforation. They record observations made both on the predisposing factors which long antedated gastric symptoms and on the external events which preceded the catastrophe. The investigations were made on fifty patients recovering from hematemesis and on twenty-five convalescent from an operation for a perforated ulcer. Regarding the fifty patients with hematemesis it was found that the precipitating events classified themselves most readily in relation to money matters, to the nature of their work and to serious illness of near relations, with a small residue of miscellaneous disturbances. Among the patients with perforation they discovered much the same personality types and precipitating situations. As in the hematemesis group, they found that the majority, sixteen of twenty-five, showed some acute episode in their lives which preceded the perforation by a few days. In nine, however, although no such events were found, symptoms of long-standing emotional stress were observable. The fact that events capable of producing unusual emotional tension were found to precede hematemesis and perforation in sixty-three of seventy-five patients appears to provide the evidence that the nervous system does play an important part in their etiology. The authors point out that patients often remark on their improvement after one of these catastrophes. The evidence points to a rapid healing following these major complications of ulcer. Does this fit in with the nervous origin of ulcer? As the authors show in their examples, these patients are harassed and worried by their responsibilities and by environmental changes. When there is acute uncertainty whether they can get through a situation or not, to give in, to resign and admit defeat is incompatible with their makeup. But when blood is vomited there is a sudden change in affairs. Their threatened failures are expiated. Urgent treatment is called for, and all other events become relatively unimportant. Wounded in the battle of life, they have an armistice and with it the possibility of a new orientation. The cares and worries of yesterday now seem relatively unimportant. It may be that this attitude of mind, this new outlook, does play some part in the good results which follow such urgent complications. If the view of the etiology of peptic ulcer implicit in these observations is accepted, there are corollaries in designing treatment. Practical therapy should include an attempt at prevention of these complications. In known ulcer patients avoidance of increased responsibility or of sudden changes in responsibility and encouragement of a more even life may help in the right direction, and during unavoidable stress and anxiety the frequent buffering of hyperacidity is rational. But in prevention by far the most important point is to convince the patient that his mind is capable of bringing distress to his stomach. Once the patient accepts this relation he can, the authors think, do much to put his house in order.

Late Sequels of Pulmonary Embolism.—Belt shows that pulmonary embolism is rarely regarded as the cause of chronic disease. Yet a careful study of the pulmonary arteries at necropsies makes it clear that sometimes it is necessary to reckon with long-standing lesions and morbid processes which appear to be the result of emboli lodged in the lungs months or even years before death. For want of a better term, the condition which the author describes may be called "chronic embolization of the pulmonary arteries." He has collected four representative cases which illustrate the progressive phases of this morbid process. The first patient, a man aged 28, sustained an injury on his left knee; the wound became infected, and the thigh had to be incised for the drainage of pus. Thereafter he had recurrent attacks of pulmonary embolism with pleuritic pain and bloodstained sputum. There were several episodes of increasing severity before the fatal seizure five months after injury. The necropsy revealed evidence of congestive heart failure, old and recent emboli of the pulmonary arteries and old and recent thrombosis of the left iliac veins. The author says that migration of venous thrombus to the lungs is seldom confined to a single event but tends to recur. This case is an example of recurrences over a period of three or four months. The emboli apparently arose from a subclinical thrombosis of the left internal and common iliac veins. This thrombosis was probably a sequel to the injury of the left leg. The second patient, a woman of 77, had recurrent attacks of pleural pain and weakness. She was treated for coronary disease and bronchopneumonia, and several weeks later she suffered two sudden painless attacks of faintness and suffocation. She died with congestive heart failure. The necropsy revealed that practically all the secondary branches of the pulmonary arteries were occluded with old and recent emboli which had arisen from a silent thrombus in the right external iliac vein. There were several small hemorrhagic infarcts of the lungs with associated pleurisy. In the third case the necropsy revealed cor pulmonale with chronic vascular congestion of viscera; fibrous stenosis of the pulmonary arteries, possibly due to organized emboli, and scarring and trabeculation of the left femoral and popliteal veins. The author emphasizes that the lesion which is regarded as an organized embolus is not necessarily static. There may be microscopic deposits of secondary thrombus on its surfaces. These tend to recur and undergo organization, somewhat like the verrucose vegetations of rheumatic heart disease, and may lead to progressive scarring; or there may be extensive development of secondary thrombus, as in case 4. In this latter case necropsy revealed cor pulmonale, old scarring of pulmonary arteries, recent emboli of the tertiary branches and a large plaquelike thrombus of the right main branch. The emboli had arisen from leg veins, which showed old and recent thrombosis. The clinical picture was not unlike that of Ayerza's syndrome. The extensive scarring of the larger pulmonary vessels probably dated back six years to a serious illness. The fatal issue was determined by embolism. The large plaquelike thrombus, which half filled the right pulmonary artery, had its roots in an old scar. It is not difficult to see how such scars as these might result from the organization of large emboli. The author stresses that, if watched for, many emboli of the lungs are seen in routine necropsies; these emboli for the most part are undiagnosed clinically. On the other hand, so few cases of primary thrombosis are seen that, when it comes to deciding between primary thrombosis and embolism, the author always thinks of embolism first, though this is not the common teaching. In all of the reported cases he proved a potential source of embolism. He thinks that if his interpretation is correct, recurrent embolism is a possible cause of chronic pulmonary obstruction and cor pulmonale. Moreover, he believes that some cases of Ayerza's disease may perhaps be explained on this basis.

Infantile Acrodynia with Gangrenous Mutilations.

According to Gadrat and his collaborators, the view long entertained of the benignancy of infantile acrodynia needs to be revised in the light of the investigations of the last fifteen years or more. They report two cases showing ulcerogangrenous complications of the extremities. The first case concerned an infant girl aged 23 months, of healthy parents and with no previous pathologic history. She had been hospitalized five months after the appearance of a general cutaneous eruption diagnosed as eczema and after the further progress of the disease had produced extreme pains, livid discoloration of the skin of the terminal finger bones and a dry gangrene that had necessitated amputation of the thumb of the left hand and implicated the loss of the third bone of the index finger. The clinical examination showed cyanotic, cold and sweaty feet and hands swollen to the wrists, the left hand enormously so, the stump of the index finger disclosing the bone and exhaling a nauseating odor. Treatment consisted of hot baths, local application of an ointment, daily injections of 0.0002 Gm. of acetylcholine and administration of two ampules of liquid liver extract and 0.05 Gm. of phenobarbital. This treatment was reinforced subsequently by ultraviolet irradiations and a vitamin D regimen. The authors' final report of the patient's condition, more than a year after inception of the infection, shows general excellent health, the right hand normal in appearance and size, the left hand well cicatrized but with only the fourth and little finger remaining and the fourth finger almost twice its normal size. The second case concerned a country girl of about 3½ years, of healthy parents. The child had had whooping cough and measles before the end of her second year, but with no complications. Two months before hospitalization she developed great pain in the extremities, swollen hands and feet, an oozing sweat and the loss of the terminal bone of the right fourth finger. Clinical examinations showed feet and hands enlarged, cold and sweaty, the fourth finger necrotic, and tachycardia with a rate as high as 160 per minute. Three days after hospitalization the child suddenly died. Necropsy revealed vasodilatation with intense congestion in all organs and a massive vacuolar degeneration of the cervicodorsal medulla resembling genuine syringomyelia. Interpreting the two cases in the light of the literature, the authors point out that infantile acrodynia complicated by gangrene and resulting in phalangeal mutilation is infrequent, that gangrenous acrodynia is not necessarily fatal and that the majority of serious mutilations occur in infants aged between 2 and 4 years. While gangrene constitutes a formidable complication of acrodynia, its prognosis does not depend directly on gangrenous manifestations. They attribute the disease to neurologic lesions without, however, being able to account satisfactorily for the modifications of the inferior cervical ganglion of the sympathetic nervous system. Acrodynia is probably due, in their opinion, to a neurotropic virus with a special affinity for neurovegetative centers and capable of causing medullar degeneration that may end in syringomyelic cavities.

Alcohol Hallucinoses and Schizophrenia.—Huber investigated twenty cases of alcohol hallucinoses in order to determine whether and to what extent relations exist between alcohol hallucinoses and schizophrenia. In all of these patients the prolonged abuse of alcohol could be demonstrated, and in five the histories revealed alcoholism in the ascendancy. Two patients presented in addition to the symptoms of alcohol hallucinoses

those of delirium tremens. In six of the patients who had had attacks of alcohol hallucinosis schizophrenia later developed, and in three other patients the hallucinosis had some schizophrenic aspects. With regard to one patient it could not be definitely decided whether in the last attack of hallucinosis a schizophrenic or a senile component was involved. The author says that it must be regarded as definitely established that the specific symptoms of hallucinosis, that is, the auditory hallucinations combined with anxiety, are the result of a direct or indirect alcohol intoxication, for in all these cases abuse of alcohol could be demonstrated and there were no cases of this type in the absence of the abuse of alcohol. In the concluding summary the author says that there are two forms of alcohol hallucinosis: a form in which only the alcoholic factor becomes manifest and which represents the acoustic counterpart of delirium tremens, and a form in which a schizophrenic factor is recognizable in addition to the alcoholic factor. The latter form becomes manifest in that the symptoms of hallucinosis assume a schizophrenic color, that is, either the characteristic symptoms of hallucinosis are based on a mode of experience otherwise characteristic for schizophrenia or a schizophrenic syndrome is added. This latter form frequently changes into schizophrenia. Whether alcohol hallucinosis is of purely alcoholic origin or whether it is a reaction that develops on the basis of a schizophrenic predisposition cannot be definitely decided. Meggendorfer's assumption that tendencies toward schizophrenia are the basis of alcohol hallucinosis seems plausible. On the other hand, it cannot be denied that alcohol hallucinosis represents an independent syndrome and that it may aid in making a latent schizophrenia manifest. This latter assumption seems to be corroborated by the fact that alcohol hallucinosis never develops in the course of an already manifest schizophrenia but always at its onset.

*Painful Hemisacralization: Pathogenesis, Diagnosis and Treatment. F. Stefani.—p. 565.

Painful Hemisacralization.—According to Stefani, pain in hemisacralization of the fifth lumbar vertebra is due to irritation of sensory osteoperiosteal sensory nervous fibers, without any nervous or radicular lesion. The sensory and motor innervation of the leg, lateral to pain, is normal in hemisacralization, whereas it is disturbed in pain of neuritic or radicular origin. The coexistence of x-ray abnormalities of the vertebra with a normal sensory and motor innervation of the leg indicates hemisacralization. The author proposes a procedure for testing the normality of innervation of the lateral leg. It consists of the administration of an injection of a small dose (not specified by the author) of an anesthetic in solution over the apex of the macro-apophysis, the presence of which is previously determined by x-ray examination of the sacrolumbar segment. The injection is made under radioscopic control, with a needle of about 8 or 10 cm. Diffusion of the anesthetic to nearby structures is avoided. Pain from hemisacralization disappears immediately after the injection. The leg regains function. Both pain and dysfunction of the leg return as soon as the effect of the anesthetic is over. Neither sensory nor motor disturbances appear in the leg in the course of or after the test (positive results from the procedure). Pain from sacralization complicated by either neuritis or radiculitis disappears after the anesthetic from the lumbosacral region and upper part of the leg, whereas it is not modified at the lower part of the leg (partial positive results from the procedure). Lumbosacral pain of either neuritic or radicular origin either is not modified or is slightly modified simultaneously with appearance of sensory and motor disturbances of the leg. According to the author the procedure is of value for the diagnosis of painful sacralization and also for deciding on the operation, which is resection of the macro-apophysis. Five cases are reported. Two patients recovered from the operation (resection of the macro-apophysis). There was one case of the mixed form and one each of rheumatic and spondylolisthetic lumbosacral pain.

Sclerogummatous Syphilis of Gastrocnemius Muscle: Case. B. Rossi.—p. 813.

Hordeine Sulfate in Treatment of Diarrhea. R. Traverso.—p. 818.

Blood Transfusion in Rheumatic Endocarditis.—Rettanni resorted to blood transfusion for ten patients suffering from febrile forms of rheumatic endocarditis. Administration of previous treatment with salicylates had controlled the articular symptoms in all cases without interfering, however, with the progress of the heart disease. The most acute symptoms were those given by the heart disorder, fever and anemia. The author administered 300 cc. of blood for each transfusion every other day until twelve transfusions had been given. In all cases the fever abated and later in the course of the treatment disappeared. The crisis of the blood and general and nutritional condition of the patients greatly improved. The cardiac condition had complete remission (up to clinical recovery) in six cases. Great improvement occurred in two. The treatment failed in two. The author believes that the results of blood transfusion in febrile forms of rheumatic endocarditis are due to several factors: the presence of antitoxic and anti-infectious substances in transfused blood and a special biologic effect of blood by which it stimulates the organic forces of defense against the condition.

*Pathology and Epidemiology of Salmonellosis in Infants. E. Hormaeche.—p. 445.

Non-tuberculous Pulmonary Diseases in Infants with Congenital Syphilis: Case. J. R. Marcos and Sara Mendivil.—p. 463.

Salmonellosis in Infants.—Hormaeche studied, in the course of the last two summer seasons, more than 200 cases of salmonellosis in infants. He found that the infection is caused by salmonellas of the group of *Salmonella enteritidis* but that the clinical picture, evolution and epidemiology of the infection are different from those of food poisoning in adults. Salmonellosis in infants is not produced by intestinal absorption of salmonella from contaminated food. Contagion takes place from convalescent adults (who suffered from enteritis). It is highly contagious among infants. However, older children and adults cannot be infected through infants. It occurs more frequently in summer than in any other season of the year. In some cases it develops with primary intestinal and gastrointestinal disturbances of progressive evolution and different type and acuteness. In other cases the first symptoms show pharyngitis or rhinopharyngitis with fever in the course of which the intestinal and gastric symptoms appear. The enteric pure forms evolve for two or four weeks with alternations of improvement and aggravation. The pharyngeal and rhinopharyngeal forms are frequently complicated by otitis media or meningitis and are grave. A salmonella of animal origin can be isolated from the pharyngeal (or rhinopharyngeal) exudates, the pus of otitis and the cerebrospinal fluid in meningitis. Septicemia may complicate the infection, the rate of mortality of which is high. According to the author the differences between the pathology and epidemiology of salmonellosis in infants and those of food poisoning in adults depend on the following factors: (1) the different sensitivity of infants and adults to the pathogenic action of salmonellas of animal origin, to which infants are highly sensitive, (2) the small number of organisms which are necessary to produce the infection in infants and (3) the pathogenic mechanism of salmonellosis in infants, which resembles that of salmonellosis in animals rather than that of food poisoning in adults. Both in infants and in animals salmonellosis is an infection, whereas food poisoning in adults is a toxicosis. Again, both in infants and in animals the infection may be primarily located in structures other than the gastrointestinal tract, which is the structure mainly involved in food poisoning. The author believes that bronchopneumonia in infants which develops in summer, when complicated by gastrointestinal disturbances, is a form of salmonellosis with primary involvement of the lungs.

*Vitamin B₁ in Treatment of Nonanginous Precordial Pain. B. Moia and F. F. Batlle.—p. 73.
Descending Aorta in Roentgen Anteroposterior Position. B. Moia and J. A. Aguirre.—p. 83.
Calcification of Aortic Valves. B. Moia and F. F. Batlle.—p. 108.

Vitamin B₁ in Nonanginous Precordial Pain.—Moia and Batlle say that there is a type of precordial (cardiothoracic) pain which has a different clinical picture and different pathogenesis from those of angina pectoris and pain from coronary occlusion. It may be either mild or acute and persistent or repeated but never paroxysmal or constant. It diffuses from the precordial region to the left pectoral region and radiates to the left arm. It may appear in persons having a normal cardiovascular apparatus or in patients with cardiovascular diseases. It develops predominantly in persons with nervous hyperexcitability. The authors, taking as a point of departure the beneficial effects of vitamin B₁ on painful symptoms which appear in certain nervous diseases, resorted to vitamin B₁ in the treatment of precordial pain in 100 cases. The cardiovascular apparatus of eighteen patients in the group was normal. Nine of the patients had neurocirculatory asthenia, seven had mitral stenosis and sixty-six had hypertension of various intensity, vascular sclerosis, coronary disorders and syphilitic aortitis. In all cases the condition dated from several years back and various treatments had previously failed. Vitamin B₁ treatment was administered every other day parenterally with the dose of 0.001 Gm. for each injection up to a total number of nine injections and in rare cases fifteen. The best results from the treatment were obtained in a group of seventy-eight patients which included persons with normal cardiovascular systems and those who were suffering from hypertension and vascular sclerosis (without involvement of the coronary arteries). Pain disappeared completely in forty cases and temporarily in thirty; eight cases the treatment failed. In the group of sixteen cases of mitral stenosis or neurocirculatory asthenia, pain disappeared completely in five and temporarily in five; the treatment failed in six. Treatment failed in the six cases of vascular sclerosis with coronary involvement. In the cases in which pain disappeared the satisfactory results have lasted up to the present (fourteen months after discontinuance of the treatment).

Perforation of Gastroduodenal Ulcer.—A review of the literature suggests, according to Büttner and Fangerau, that most authors regard perforation in the course of an x-ray gastrointestinal study as a result of a combination of unfavorable factors, among which the administration of too large a quantity of the contrast meal and the diminished muscle tonus of a dilated stomach play the leading part. In the case described by the authors there existed a long standing duodenal ulceration with a high grade pyloric stenosis and dilatation of the stomach. Barium mixture was given on the first and on the third day of examination. Perforation took place one half day later. In addition to the pyloric stenosis the patient had, as a result of a previous operation for ileus, a double-flint anastomosis in the transverse colon. Inspissated barium partially obstructed the colonic anastomosis and aggravated the gastroduodenal distention. Animal experiments of Himmelmann and Paas demonstrated that the spilling of a contrast meal of the gastric contents, Neeropsy in the authors' case revealed a diffuse, hemorrhagic, fibrinopurulent peritonitis. Almost all of their cases were duodenal ulcer perforations located close to the pylorus and causing partial obstruction. A simple closure of the perforation tended to increase the obstruction. The added

gastro-enterostomy carried out in the friable ulcerated area did not always relieve the situation. It is for these reasons that the authors prefer to carry out a gastric resection provided the patient is in good condition and the perforation is an early one.

Serum Therapy of Poliomyelitis.—Gildemeister says that in Germany the collection and preparation of convalescent serum for the treatment of poliomyelitis is arranged in such a way that serum is obtained only from those persons who have had the paralytic form of poliomyelitis. It is withdrawn at the earliest two months and at the latest ten years after the attack of the disease. The quality of these serums, that is, their content in virus-neutralizing protective substances, differs greatly, even though some equalization is produced by the mixture of several serums. Thus there are mixed serums with good and some with deficient antibody content. Moreover, in patients with the paralytic forms of poliomyelitis the formation of protective substances is much inferior to that which takes place in the nonparalytic and in the abortive forms. Morevoer, it has been said that high antibody contents are encountered in persons from the environment of patients with them. The author decided to verify these reports. He determined that storage for a year, provided of course the serum is kept under suitable conditions, does not noticeably impair the antibody content. The addition of the usual conserving substances was likewise found to be without effect on the antibody content. The author describes the method he employed in the examination of the virus-neutralizing power of four different groups of serums and then reports the results of his investigations. His neutralization tests demonstrated that only half of the convalescent serums from patients with paralytic or nonparalytic poliomyelitis or of the serums of persons from the environment of such patients contain noticeable quantities of protective substances, that serums from patients with nonparalytic forms of poliomyelitis had a higher therapeutic value than had the serums of patients with the paralytic forms, and that serums of persons from the surroundings of patients with poliomyelitis had the least protective value. Serums from the retroplacental blood of healthy women had a surprisingly high protective value. The author concludes that the serum from the meningitic forms without paralysis is best for the treatment of poliomyelitis. To be sure, it will be difficult, if not impossible, to secure adequate quantities of this serum, even aside from the unreliability of the diagnosis of the nonparalytic forms of poliomyelitis. This proves that it is necessary to continue the collection of convalescent serum from patients with the paralytic forms of poliomyelitis. However, serum from nonparalytic cases should be collected, so far as the diagnosis is certain. Only mixed serums should be used for treatment, since only mixture of a number of serums will insure the presence of protective substances.

Intracutaneous Test for Vitamin C Supply.—After directing attention to the desirability of a reliable indicator of the adequacy of the vitamin C content of an organism, Beck and Krieger show that among the numerous methods which have been suggested for this purpose there are some which

determine the reduction capacity of the urine, others evaluate the vitamin C content of the blood and still others employ tolerance tests. These methods, although suitable for clinical use, have found little application in general practice. It seemed desirable to determine the adequacy of the vitamin C supply by means of a cutaneous test. The authors point out that Rotter employed for this purpose a wheal test with four hundredth normal dichlorophenolindophenol solution. The time required for the discoloration of this wheal indicates the degree of saturation of the tissues with vitamin C. The authors describe their own method of preparing the four hundredth normal dichlorophenolindophenol solution and then describe their experiences with this test on healthy persons as well as on patients in whom C hypovitaminosis was suspected. Their investigations with and without control by simultaneous tolerance tests indicated that this method is adequate for practical purposes. They found that the normal discoloration time of a wheal produced according to their technic is around ten minutes; the threshold value between the average and the inadequate vitamin C supply is between ten and twelve minutes. If the discoloration time is considerably longer, it indicates a vitamin C deficiency; if shorter it indicates saturation. Although the method can be used for practical purposes, it cannot replace the clinical scientific investigations, especially the tolerance test. In studies on the newborn and their mothers, the test disclosed a considerable degree of uniformity of the discoloration time.

Familial Amyotrophic Lateral Sclerosis.—Curschmann reports the history of a woman, aged 74, who related that as a young girl she had had paresis and muscular dystrophy in the forearms. The increase in the muscular atrophies was extremely slow, so that until six years before he saw her the patient was able to work with her hands. Impairment of the ability to walk dated back only a few years. Severe degenerative muscular atrophy was noticeable particularly in the radial region, but the other muscles of the hand and arm also were involved. The electrical irritability was practically abolished in the atrophic muscles. The muscles of the shoulder and pelvic regions were unimpaired. The patient died of cardiac insufficiency, pyelocystitis and pneumonia. The microscopic examination of the spinal cord corroborated the diagnosis of progressive spinal muscular atrophy, although the expected degenerative changes in the lateral pyramidal tracts and in the anterior tracts could not be observed. This is surprising, since some of the symptoms indicated involvement of these tracts. Especially noteworthy are the early onset, the slow progress, the comparatively mild course, the predominant involvement of the radial region and the absence of the bulbar paralysis. However, of primary interest is the fact that the brother of the patient developed during his youth the same form of muscular atrophy in his arms and legs. The author is convinced that this is an example of progressive amyotrophic lateral sclerosis in two siblings. A review of the literature, especially that of recent years, revealed to the author that the familial occurrence of amyotrophic lateral sclerosis is not as rare as was formerly believed. Among others he cites Kalinowsky, who observed a mother with amyotrophic lateral sclerosis, whose two daughters had a bulbar paralytic syndrome with atrophy of the small manual muscles; Kreyenberg, who detected amyotrophic lateral sclerosis in three siblings; Montanaro and Lopez, who observed amyotrophic lateral sclerosis in a father and three sons, and several other authors who made similar observations. He thinks that in the future careful neurologic studies should be made on the members of the families of patients with spinal amyotrophy and with amyotrophic lateral sclerosis and that studies on twins should also give attention to this group of disorders.

Electric Shock Therapy for Schizophrenia.—In order to avoid some of the dangers of the treatment with metrazol and yet obtain its favorable therapeutic results, Sogliani tried electric shock therapy, which was first described by Cerletti and Bini. The apparatus which the author employs utilizes the available alternating current, which, by means of a transformer, is brought to the desired tension. The current is passed through the head of the patient by means of a hood with two metal electrodes, which are attached to the temples. The author kept the tension constantly at 110 volts and adjusted the main contact breaker in such a manner that not more than 400 milliamperes passed through. The time necessary for the production of the convulsive attack he determined in each case by first passing the current through for half a second and then, after an interval of from ten to fifteen seconds, he repeated the electrical discharge for a time sufficient to elicit the convulsion. The thus determined optimal length of time which each patient required for the passage of the current in order to elicit the convulsion was subsequently employed for the elicitation of all attacks. The majority of patients required from 0.7 to 0.8 second for the passage of the current. The convulsive attacks thus elicited by electric shock are similar to those elicited by metrazol, but there are also differences in that, after the passage of the current, loss of consciousness results at once and the patient stretches in clonic convulsion without the cry so often heard in the metrazol convulsion. Furthermore, even in the rare instances in which an interval elapses between the passage of the current and the convulsion, the patients do not show the expression of fright and terror with dilatation of the pupils and rigid stare which they do at the onset of the metrazol shock. Moreover, the state of excitation so frequently seen after the metrazol convulsion is absent after electric shock. The electric shock can be repeated without danger after a few minutes. When the patient is about regaining his consciousness, the current may be passed through again to elicit a new convulsion. In physically healthy subjects the author elicited four or five convulsions in this manner. He gives the electric shock treatment every second day. The total number of treatments required varies between five and thirty. The first favorable results are usually noticeable after from three to ten attacks or they entirely fail to develop. Nevertheless the author subjects every patient to at least twenty attacks and after a certain interval he begins a new series of treatments. He reports the results he obtained with electric shock therapy of 100 patients. Of seventy-three patients with schizophrenia, fifteen were cured, three improved and fifty-five were not influenced. This shows that the percentage of cures did not exceed that of spontaneous regressions. However, the schizophrenic patients subjected to shock therapy belonged nearly all to that group of chronic patients who neither exhibited spontaneous regression nor had been improved by other methods of treatment. Of the twenty-seven patients with manic depressive psychosis, twenty-two could be discharged; that is, 81 per cent. This high percentage is even more impressive if the duration of the disease is taken into consideration, for among those who were cured there were several who had been institutionalized for several years. In view of this fact, the author recommends the use of electric shock therapy for old cases of depressive psychosis in which other therapeutic methods have failed.

Vitamin B₁₂ in Treatment of Hypovitaminosis. Ida Czukrász.—p. 221.

Corneal Ulcer and Sulfanilamide.—Roggenkämper says that for a period of six months he treated all cases of corneal ulcer with sulfanilamide. The substance was given internally and by subconjunctival injection, but the author did not neglect to employ also the former therapeutic measures, such as shock therapy in the form of intramuscular injections of milk and the customary local methods. Thus the subconjunctival injection

of sulfanilamide was an auxiliary measure in the twenty-six cases on which this report is based. In fifteen of the twenty-six cases there existed posttraumatic serpiginous ulcers of various ages and extension, and in nearly all of them hypopyon existed. In all these cases the therapeutic results were surprisingly favorable as regards rapidity of cure as well as the final results. Among these cases of serpiginous corneal ulcers there were some which at the time of hospitalization gave the impression that only splitting of the cornea would prevent a panophthalmia. However, treatment with sulfanilamide made this unnecessary. The delicacy of the resulting corneal scars and the visual acuity were surprising. This applies to new cases in which the ulcers yielded to from one to three injections as well as to old cases in which nearly all hope had been abandoned and in which from six to eight injections of 0.5 cc. each were necessary to produce epithelization. Surgical operations were unnecessary and the author regards this as an essential advantage of the sulfanilamide therapy. In the scrofulous and catarrhal ulcers of the cornea the effect of the subconjunctival injections of sulfanilamide was not as favorable as in the typical serpiginous traumatic ulcers, but even there a favorable effect could be noticed. It is possible that the bacterial superinfection of these ulcers was excluded by the sulfanilamide. Favorable effects of subconjunctival injections of sulfanilamide were observed also in two cases of persistent parenchymal infiltrations following erosions and in three cases of infected erosions. In superficial keratitis, however, no effect was noticeable. The author concludes that sulfanilamide is of great value in infectious corneal diseases and that in serpiginous ulcers it may make surgical operations superfluous.

Sulfanilamide in Gonorrheal Eye Diseases.—The favorable results obtained with sulfanilamide in cases of gonorrhea induced Kattiofsky to try this treatment in four cases of gonorrheal conjunctivitis of the newborn. Fearing the toxic effects of the oral administration of sulfanilamide, he decided to apply it locally in the form of an ointment. He found that the therapeutic results of the local administration of sulfanilamide were not better than those of the customary therapy. However, he cites investigators who observed favorable results from the oral administration of sulfanilamide in the gonorrheal conjunctivitis of the newborn. He further describes the clinical histories of two adults with gonorrheal eye diseases. Favorable results in both of them were obtained with the oral administration of sulfanilamide. The author concludes that the chemotherapy of gonorrheal eye diseases by means of sulfanilamides represents a valuable addition to the therapeutic possibilities in these disorders.

*Clinical Aspects and Diagnosis of Chronic Traumatic Hernias of Diaphragm. H. Brandt.—p. 1312.

Traumatic Hernias of Diaphragm.—Brandt says that traumatic diaphragmatic hernia, that is, the displacement of abdominal viscera through an opening into the thoracic cavity, is usually a false hernia, because it is not surrounded by a hernial sac. Nevertheless, in case of tangential bullet wounds, true diaphragmatic hernias have been observed in that only the diaphragmatic pleura or only this pleura together with the musculotendinous tissue was injured, while the peritoneum was not opened. The clinical aspects of traumatic diaphragmatic hernias vary greatly. On the basis of material from the literature, the author differentiates two main groups, the acute and chronic diaphragmatic hernias. The acute traumatic hernias of the diaphragm he classifies into those with and without signs of incarceration. In this report he takes up the chronic traumatic hernias of the diaphragm. He gives detailed clinical histories of two cases. The first patient had sustained injuries in an automobile accident. With the exception of occasional drawing pains

in the epigastric region after big meals, the patient felt well for more than a year after the accident. Then he developed acute symptoms. At first diaphragmatic hernia was not thought of because there had been no trauma in the thoraco-abdominal region. Finally the condition was diagnosed as gastric volvulus and an operation was performed. Two days later the patient died. The surgical observations and the necropsy indicated that the accident caused a tear in the diaphragm and that the prolapsing omentum became fixed by adhesions. The occasional symptoms may have been caused by dragging or temporary incarceration of the stomach in the tear. It is not probable that the stomach had been in the thoracic cavity uninterruptedly since the accident. The necropsy disclosed a diaphragmatic tear 8 cm. in length, and it is assumed that at the time at which the acute symptoms began a portion of the bloated stomach passed through the tear and, as a result of the suction exerted by the negative pressure in the thorax, the stomach was drawn more and more into the thorax and was incarcerated in the diaphragmatic slit. A spontaneous return of the stomach was made impossible because it had been turned in such a manner that the great curvature was located forward and above. The second patient had sustained an accident which had produced a pelvic fracture and internal injuries. Here again the trauma did not involve the thoraco-abdominal region directly. The operation disclosed a diaphragmatic opening the size of a fist through which parts of the stomach and of the intestine entered the pleural cavity. This patient had severe symptoms continuously. The author shows that the hernias of the two patients represent two different types of chronic traumatic diaphragmatic hernia. The first patient had that form which exists for a long time without disturbances but in which an incarceration may suddenly cause severe symptoms; the second patient had the form of chronic diaphragmatic hernia which constantly causes symptoms. In the conclusion the author stresses among other points that, even if a trauma did not directly involve the thoraco-abdominal region, the possibility of a diaphragmatic hernia should be thought of whenever the abdominal organs cause symptoms in these cases. It should also be considered that a symptom-free interval may exist between the injury and the appearance of signs of incarceration.

Afuction in Atrophic Gastritis. A. Mahlo.—p. 1341.
Effect of Ephedrine on Muscle Activity. A. Szakall.—p. 1344.

Subarachnoid Hemorrhages.—According to Landes, the classic picture of what is generally designated as subarachnoid bleeding is characterized by violent cephalalgia, sudden loss of consciousness, physical collapse in apparent health, marked meningeal signs and the bloody appearance of the cerebrospinal fluid in lumbar puncture, together with a high frequency of mortality reported in earlier medical experience. On the basis of eight cases—there were six men and two women between the ages of 18 and 66, with seven cures after an average clinical management of five weeks (treatment not indicated) and one fatality—the author calls attention to the variability of the characteristics, neurologic as well as clinical, in the symptomatology of this disease. Lumbar puncture, initially performed, yielded a sanguineous fluid with pressure as high as 400 mm. of water. In subsequent assays the fluid appeared clearly xanthochromic. Initial erythrocytic counts numbered uniformly from 40,000 to 50,000; after eight days erythrocytes were no longer discernible. No initial preponderance of leukocytes, a typical sign of hemorrhagic meningitis, was observed. However, in most cases, contrary to the literature, leukocytic calculation was essentially higher, amounting to from 600 to 11,000 leukocytes per cubic millimeter, and after a week and later still yielded from 60 to 80 per cubic millimeter. Carefully conducted bacteriologic investigations, extended to include detection of anaerobic agents, remained negative. In three cases albumin in the spinal fluid was out of proportion to the blood content. The sugar content was generally high and averaged 80 mg. per hundred cubic centimeters. Syphilis was clinically excluded. Psychologic changes observed in all cases ranged from initial states of confusion and disorientation as to time and place to

considerable disorders of the memory and the faculty of attentiveness and lasted in some cases as many as four months. Necropsy performed in the single fatal case revealed local softenings with red infarct in the right temporal lobe and perforation of the lateral ventricle, microscopy indicating a dense leukocytic barrier about the infarct. Etiologically considered, death in this case may be accounted for as due to serious vasomotor disturbances. In the analysis of the other cases, the author's conjecture ranges from an aneurysm at the base of the brain to a causative agent of more inflammatory nature. Long continuing mental disturbances may indicate encephalitic processes in which the soft meninges are involved. Genuine hemorrhagic meningitis is not assumed. The author inclines to regard subarachnoid bleeding as a syndrome rather than a disease entity with a uniform etiology.

 Chronic Appendicitis as Related to Gastric Duodenal Disorders. O. G. Plisan.—p. 616.

Congenital Cerebral Hernia.—Sokolov has reviewed all cases of congenital encephalocele reported by Russian surgeons. Of the 143 patients, 119 underwent an operation; of these forty-three died, the mortality rate being 36.1 per cent. Of the 107 patients with frontal ethmoid encephalocele thirty-six died (33.6 per cent); in three the results seem doubtful (2.8 per cent). Recovery was obtained in sixty-eight (63.6 per cent). The author reports eight cases observed by himself and offers his own hernia plastic technic. His conclusions are as follows: 1. The frontal ethmoid encephalocele is more common in the Soviet Republic, the occipital variety being rather rare. 2. Infants with frontal ethmoidal cerebral hernia display remarkable viability. 3. Infants with cystic encephalocele should be operated on at the earliest possible time, even during the very first days of life. In doubtful cases treatment may be postponed till the infant is a month old, but it should always be performed in the first year of life. 4. In cases of considerable bony defect the symptoms may seem grave, but they disappear after the plastic closure of the defect. 5. The inner opening of the bony canal in nasofrontal hernia has unequal axes, the transverse axis usually exceeding the rest; this is especially true in naso-ethmoid hernia. The shape of the inner opening of the bony canal approaches an oval, the edges being fairly even. 6. The author recommends one stage, external operation, the procedure for posterior orbital hernia being an exception to the rule. 7. In naso-ethmoid and nasofrontal encephalocele the closure of the inner opening of the canal with a bony graft inserted from the inside of the skull insures good results. The access to the inner opening is gained by means of mobilizing the anterosuperior and partly the lateral walls of the bony canal. A graft of a size exceeding that of the defect and completely covering it can be introduced into the cranial cavity without any difficulty, for which purpose the difference in the axes of the canal is made use of. 8. In the anterior orbital hernia the short narrow canal should be completely eliminated by the introduction of a pinlike cartilaginous graft. 9. The author believes a free bony autoplasmic graft to be the best material for the closure of large defects in encephalocele, the cartilaginous autoplasmic graft being the best in smaller defects.

Eye Symptoms in Leiodystonia and Sprue.—Pock-Steen calls attention to eye symptoms that he observed in about 100 patients with leiodystonia, sprue and sprue-like disorders. The most noteworthy eye symptom was a reduced visual acuity

during weak daylight, such as twilight and during inadequate artificial illumination. The author designates this symptom as twilight blindness or aknephascopia. The twilight blindness is due to a diminished susceptibility to the light waves. It differs in nature from the well known night blindness. It is not influenced by the administration of vitamin A, as is night blindness, but it is greatly ameliorated a few hours after the administration of approximately 1 mg. of riboflavin (vitamin B₂). Of 109 patients, sixty-seven stated without hesitation that their vision was greatly improved following the first injection of 1 mg. of riboflavin, whereas thirty-one were able to corroborate this only after a longer period. The remaining eleven patients observed only a slight improvement in their visual acuity. The author observed that the symptoms of twilight blindness were usually greater in those patients with sprue who had anomalies of refraction. In these cases the effect of riboflavin on the visual acuity was not always as favorable as in the cases of sprue without anomalies of refraction. Nevertheless even in these cases surprisingly favorable results were obtained. In this connection the author mentions a patient aged 64 who stated that in two years he was obliged to change his glasses three times for stronger ones, but after his sprue had been treated with injections of riboflavin he could return to the use of his first pair of glasses. The author thinks that the twilight blindness is a symptom of a general B₂ hypovitaminosis and the only one known that can be observed clinically. Other eye symptoms observed in sprue are mydriasis, conjunctival irritation, keratitis and disturbances of accommodation. The burning pains of conjunctivitis were also found to decrease after the administration of riboflavin. The author thinks that the eye symptoms of patients with sprue are partly the result of B₂ hypovitaminosis and partly the consequence of the histamine toxicosis prevalent in sprue.

 Treatment of Migraine. C. T. van Valkenburg.—p. 4412.

Syphilis Resistant to Therapy.—Ruiter cites observations made in a small town in which no new cases of syphilis had been observed for a number of years. Then a primary infection was discovered in a prostitute coming from another town, and subsequently there was an epidemic of syphilis. This outbreak of syphilis was noteworthy because of the high percentage of cases that proved resistant to chemotherapy. The author describes the histories of eight patients, in six of whom there developed, in the course of their treatment, a resistance to chemotherapy. The majority of the patients whose syphilitic infection proved refractory to chemotherapy exhibited psoriasisiform papules, one patient had a pustulous rash with distinct mucosal lesions, and in one patient with drug-resistant primary syphilis a malignant type of syphilis developed. In spite of florid skin lesions, the serologic reactions were often found negative. The author mentions the types of chemotherapeutic substances that were used, also the doses given and the intervals that elapsed between administrations. He shows that with the exception of the first patient, who proved resistant to neoarsphenamine and sodium arsphenamine but who showed some response to bismuth, all patients had a resistance to plurivalent therapy. The fact that two drug-resistant women who were treated with arsenicals during pregnancy gave birth to healthy children seems to indicate that an arsenicoresistant variant of *Spirochaeta pallida* could be excluded. Nevertheless, the author assumes that the spirochetes contributed to some extent to the high incidence of resistance to chemotherapy. In remarks about how the resistance to drugs can be counteracted in syphilitic patients, the author mentions E. Hoffmann's method and the "saturation" treatment of Sehreus. Furthermore, in some cases changing of the preparations or strengthening general treatments might prove helpful. If the resistance is plurivalent total, the author recommends a trial with fever therapy.

had been prescribed in five. Recurrences sometimes appeared fairly soon, but generally the improvement lasted for several months after the treatment. The results were encouraging and the method is recommended for further trial.

Acid-Fast Bacilli as Source of Error.—Lester points out that the acid-fast saprophytes deserve attention because they belong to the myobacteria and are closely related to the tubercle bacilli. She decided to determine the frequency of occurrence of acid-fast saprophytes in the specimens submitted for bacteriologic diagnosis. During the five years from 1932 to 1936 inclusive, 26,343 specimens were examined at the tuberculosis department of the State Serum Institute of Copenhagen and 130 acid-fast saprophytic bacilli were isolated. An increase in the number of acid-fast saprophytes was seen following two improvements in the technic: the change from Petroff's medium to an egg asparagin medium containing 0.75 per cent of glycerol and the replacement of sodium hydroxide by 6 per cent of sulfuric acid for homogenization. The author describes the methods that are used for differentiating saprophytic acid-fast bacilli from tubercle bacilli and shows that three procedures proved valuable: (1) prolonged observation of the primary culture, (2) subculture on solid egg medium and in Besredka's fluid medium and (3) intracutaneous inoculation into guinea-pigs. Some strains of special interest are described in detail. No attempts are made to classify the acid-fast saprophytic bacilli, as no adequate serologic or biochemical methods are as yet available. In fifty-five of the 130 strains the colonies had a bright orange color. It is not possible to determine if they form a group apart, but these strains seem at least to have some features in common. None of the 130 strains were pathogenic for guinea pigs in the doses used, but the most dysgonic of those growing in orange-colored colonies produced small abscesses following intracutaneous injections. No propagation was seen, and the abscesses healed spontaneously in a few weeks. Some of those strains were examined by injection of higher doses into guinea pigs and rabbits, but only local regressive lesions were seen. One avian tubercle bacillus was included in the material. Culturally it showed some resemblance to the dysgonic chromogenic saprophytes, but, by virulence tests in guinea pigs and rabbits, it was classified as a typical avian tubercle bacillus. Only about one fifth of the strains observed by the author resembled the eugonic, more or less pigmented cultures most often described in the older literature as acid-fast saprophytic bacilli. The source of the saprophytes found in cultures from human material could not be determined. In some cases it seemed probable that the saprophytes were brought into the specimens at the hospital, in a few other cases the laboratory had to be suspected. The author emphasizes that in diagnostic work it should always be remembered that many of the acid-fast saprophytes greatly resemble atypical tubercle bacilli, which, however, are rare. A strain that cannot be definitely identified as a human or bovine tubercle bacillus should not be discarded until it has been thoroughly examined by cultural and animal tests.

Tuberculous Cavity of Lower Lobe.—Törning and Springborg show that when the treatment is to be selected not only the size and the pathologic-anatomic character of a tuberculous cavity but also its localization must be considered. In view of the fact that roentgen examination is generally limited to one plane, the frontal, it has been possible to localize the cavity only in this one plane. The current terminology shows that this limitation has been forgotten, for most of what has

been written of "central" cavities is based on the observation of cavities which in the frontal pictures were located medially, near the hilus, while they might very well have been peripheral, situated immediately beneath the anterior or posterior surface of the lung. A more precise localization of the cavity requires roentgen study in several planes. In this paper the authors give an account of cases that met two requirements: (1) There was a cavity measuring at least 2 cm. in diameter and located below the level of the pulmonary artery at the hilus of the lung; (2) the pulmonary lesion was entirely unilateral and apart from the cavity there was nothing pathologic in the lungs (nineteen cases) or merely small, sharply defined shadows that could be interpreted as signs of a healing process (two cases). The authors give brief histories of these twenty-one cases and indicate in sketches the localization and the size of the cavities. In fourteen of the twenty-one cases in which the solitary cavity below the level of the pulmonary artery could be located exactly, it was situated posteriorly in the lower lobe. The juxtahilar ("central") cavities, four altogether, were all markedly peripheral, situated posteriorly in the lung. Of seventeen patients treated with pneumothorax an adhesion-free pneumothorax was obtained primarily in nine and after cauterization in four. These patients are all well. Of three patients with noncauterized adhesions to the area of the cavity, two died. Whenever an adhesion-free pneumothorax was obtained the results were just as good in patients with large cavities as in those with small cavities. When there is a solitary cavity and the process of infiltration is limited to the circumference of the cavity, if active treatment seems indicated, it should always commence with an attempt at pneumothorax, regardless of the location and size of the cavity.

 Duration of Confinement to Bed after Operations. N. Backer-Grøndahl.—p. 2630.
 Short Wave Therapy of Salpingitis. H. F. Dahl.—p. 2632.

Aneurysms in Brain.—Hval cites Römcke and Ustvedt, who report from Ullevaal Hospital that subarachnoid hemorrhages occur in one of every twenty-nine apoplexies and that of their twenty-seven cases fourteen involved persons under 50 and eight persons under 30. A large number of such hemorrhages, Hval says, are due to rupture of aneurysms at the base of the brain. The aneurysms are usually of the size of a pea or smaller; careful examination is necessary to establish them. Since subarachnoid hemorrhages often lead to death in apparently well persons in the prime of life they are important in medicolegal cases, and traumatic aneurysms are of special interest. In the first of the five cases of subarachnoid hemorrhages described, in a man aged 23 who died sixteen days after trauma of the head, necropsy showed unusual and marked changes in the vertebral artery, together with a process undergoing organization and the development of a pseudo-aneurysm at the site of the rupture. If the fatal hemorrhage had not occurred, a permanent aneurysm would probably have resulted ("traumatic aneurysm"), although the vascular changes were of primary importance. In the other cases pea-sized aneurysms had ruptured. In one case the aneurysm was in the middle cerebral artery and due to arteriosclerosis; in one case in the anterior cerebral artery, with degenerative changes in the vascular wall and calcifications in the internal elastic membrane, and in two cases in the inferior posterior cerebellar and the left posterior cerebral artery, respectively, with syphilitic endarteritis and leptomeningitis and calcifications. In the sixth case presented, sudden death occurred after a cerebral tumor probably in the hypophysis had been suspected. An aneurysm the size of a pigeon's egg was found in the circle of Willis adherent to the optic chiasm and extending from the right posterior communicating artery. The ventricle system was filled with blood. There were no signs of arteriosclerosis or degenerative changes in the blood vessels, and congenital origin of the aneurysm is thought possible.

SOME CLINICAL NEUROLOGIC ASPECTS OF VITAMIN B DEFICIENCIES

CHARLES D. ARING, M.D.

JOSEPH P. EVANS, M.D.

AND

TOM D. SPIES, M.D.

CINCINNATI

Vitamin B₁ (thiamin, aneurin, catorulin) and nicotinic acid are the only components of the vitamin B complex which are known to be of significance in the maintenance of normal neurologic function, in man (fig. 1). The use of these substances in the treatment of various neurologic diseases will be discussed in this presentation. A discussion of the diagnosis of the neurologic diseases incident to a deficiency of these substances must be slighted because of the limitation of space.

VITAMIN B₁

Neuritis.—Neuritis means disease of the neuron (Brown¹). The principal causes of neuritis may be grouped under six inclusive headings, given in the accompanying table, as has been done by Cobb and Coggeshall.² As the causes of neuritis are better understood, such clinical classifications will be replaced by classifications based solely on etiology.

Localized Neuritis: This type of neuritis usually occurs in ambulatory patients, and the mechanical or infectious agent can often be determined by clinical methods. The symptoms usually respond to medical and surgical therapy. Relief of localized neuritis following the administration of crystalline vitamin B₁ has been reported by some investigators. Such reports, however, tend to be misleading, since physicians who obtain negative results are less prone to report them. Furthermore, the number of reported cases is small, and in general the studies have not been adequately controlled. Hence the results need confirmation. Likewise, no conclusive reports have as yet appeared in the literature concerning the value of vitamin B₁ in the prevention of localized neuritis.

We have observed the relief of the acute pain in a case of brachial neuritis occurring six weeks after mastectomy, with the use of daily intravenous injections

of 50 mg. of vitamin B₁³ in sterile physiologic solution of sodium chloride for seven days.

Generalized Polyneuritis: Virus Polyneuritis. The virus diseases listed in the table are often characterized or accompanied by peripheral neuritis as a late complication. No crucial observations have been made to determine whether faulty nutrition plays a role in the development of the neuritis seen in these diseases. The small amount of experimental evidence available tends to show that vitamin B₁ does not play any direct specific role in counteracting the effects of these infectious agents.

Our experience with three cases of infectious polyneuritis has been that some of the neurologic symptoms have progressed despite large intravenous doses (50 mg. twice a day) of thiamin.

Bacteriotoxic Polyneuritis. The diseases in this group often interfere with proper nutrition and thus predispose the patient to the development of a deficiency of vitamins. Many patients with an infection also have an increased requirement for certain essential nutritive substances. In typhoid, for example, the requirement for vitamin B₁ is increased because of the fever, loss of appetite or excessive diarrhea. The incidence of peripheral neuritis in patients with typhoid was high a few decades ago, when an effort was made to restrict the diets of such patients. The great decrease in the incidence of peripheral neuritis in typhoid in recent years is probably due to prescription of adequate diets in the treatment of that disease. There is little information concerning the role of vitamin B₁ deficiency in the development of any of the neuritides accompanying bacteriotoxic diseases, but a number of reports have indicated that the administration of vitamin B₁ often relieves the symptoms of neuritis in these cases. It is known that the neuritis of certain persons with infectious diseases disappears after the administration of a well balanced diet.

The neuritis accompanying acrodynia possibly belongs under this heading. Durand, Spickard and Burgess⁴ reported the cure of acrodynia in two children following intramuscular injections of vitamin B₁.

Chemical Polyneuritis. There are many chemical substances which may produce peripheral neuritis. Not every person exposed to the same chemical agent, however, responds in an identical manner. There is clinical evidence showing the predilection of some of these substances for special portions of the nervous system.

The course of two cases of triorthocresyl phosphate poisoning (jamaica ginger paralysis) shortly after the onset of symptoms was unaltered by the use of large amounts of crystalline vitamin B₁ by mouth. One of the

patients received 20 mg. daily for one month, and the other received 500 mg. daily for the same length of time. It is theoretically possible that large amounts of vitamin B₁ crystals given before the ingestion of triorthocresyl phosphate might act as a protective agent. It has been reported that the administration of vitamin B₁ causes relief of the symptoms of the neuritis following exposure to toxic agents such as nicotine, lead, thallium, arsenic and mercury. As yet, however, there is no conclusive evidence that the lack of vitamin B₁ plays a major role in the development of any of the "chemical neuritides."

We have noted improvement in a case of emetine neuritis following the administration of large doses of vitamin B₁, first given intravenously in sterile physiologic solution of sodium chloride and then by mouth. The relief was marked after the first day of treatment, and there was complete relief of symptoms at the end of the third month of treatment. We have been unsuccessful

in relieving the neuritis of a young man, a worker with refrigerants. The most likely offender in this case was methyl chloride.

addicted to alcohol, Korsakoff's syndrome develops. This clinical syndrome is characterized by a peripheral neuritis which is identical with that of beriberi and by a psychosis often resembling the mental changes seen in pellagra.

We have had experience with the neuritis of pellagra, pernicious anemia, beriberi ("alcoholic and nonalcoholic neuritis"), tuberculosis and pregnancy. These neuritides, excepting possibly the neuritis encountered in pernicious anemia, respond promptly to large doses of vitamin B₁. We usually administer thiamin intravenously, giving 50 mg. twice a day for one week. The initial response to this treatment is usually rapid. Pain is usually greatly relieved within twenty-four hours, and strength, accuracy and speed of movement are usually improved within three days, this improvement possibly being due to the conspicuous relief of pain. If analgesics have been used they may often be discontinued at this time, and patients who have slept little or not at all for weeks may be able to sleep with no medication other than vitamin B₁. The relief which usually occurs in this group of nutritional deficiency neuritides is abrupt and dramatic. Patients previously

Principal Causes of Neuritis

successful in relieving the neuritis of a young man, a worker with refrigerants. The most likely offender in this case was methyl chloride.

Nutritional Deficiency or Metabolism Polyneuritis. There is a long list of diseases in which polyneuritis, when it occurs, is conspicuously related to a lack of proper nutrition. This list is composed chiefly of metabolic and deficiency diseases, which often have a number of clinical features in common. In a presentation of this scope we are concerned chiefly with the neuritis manifestations of patients having any of these diseases.

Evidence is accumulating which indicates that many of the neuritic symptoms listed under various syndromes are clinical variations of one large etiologic group. Since vitamin B₁ will usually relieve the manifestations of the polyneuritis of beriberi, a known dietary deficiency disease, and since it is essential for the integrity of the nervous tissue in general, it seems likely that its absence may play a very important part in the development of neuritis in a number of these diseases in addition to beriberi. Evidence indicates that vitamin B₁ is a useful therapeutic agent in the treatment of "alcoholic" neuritis, with or without pellagra, of the

bedfast may be able to walk within a few weeks. However, the patient quickly reaches a stage beyond which thiamin will not cause further improvement, and residual changes may persist indefinitely.

It is our thought that the initial prompt improvement with thiamin in cases of nutritional deficiency is humoral

Fig. 1.—Differentiation of the components of the vitamin B complex. The components that have been isolated in a pure state are indicated in heavy lettering; those which have been recognized only by the discrepancies in physiologic properties of various crude extracts are indicated as loops; the possible, still unknown factors are divided into three main strands according to the principle of adsorbability, which has been so useful in differentiation experiments (from Williams and Spies, Vitamin B₁, New York, the Macmillan Company, 1938).

in nature. This impression is furthered by the work of Minz,⁵ who has been able to show that vitamin B₁ enhanced the effect of acetylcholine in the transmission of the nervous impulse. It seems that vitamin B₁ inhibits cholinesterase in the same manner as does physostigmine. In our cases in which this test was performed (in vivo) the serum cholinesterase was inhibited by the administration of thiamin. Glick and Antopol⁶ obtained similar results with horse and rat serum (in vitro), and they made the important observation that the inhibition of the serum cholinesterase was obtained only with concentrations of vitamin B₁ in excess of those known to occur in the living organism.

We have studied the peripheral nerve histologically by the biopsy method in twelve cases of deficiency disease with neuritic symptoms, in several instances both before and months after treatment with crystalline vitamin B₁. In all cases marked loss and degeneration of myelin sheaths was observed in the terminal portions of the internal branch of the anterior tibial nerve

(figs. 2, 3 and 4). The axons in these peripheral nerves have been, on the whole, normal. In cases in which the peripheral nerve was examined as long as eleven months after treatment was instituted, the loss of myelin sheaths was severe.

This study lends support to the hypothesis that the initial spectacular improvement following vitamin B₁ therapy which is experienced by sufferers from nutritional neuritis is on a humoral basis. It also illustrates how slowly restitution of the nerve may occur.

In ten cases of moderate nutritional neuritis the administration of cocarboxylase⁷ (phosphorylated thiamin), 10 mg. in sterile physiologic solution of sodium chloride twice daily by intravenous injection, resulted in the same improvement that had been seen following the use of thiamin. This result supports the hypothesis that vitamin B₁ may be utilized as cocarboxylase by the body.⁸

NICOTINIC ACID TREATMENT OF PELLAGRA

Mental changes as a part of the pellagra syndrome have been recognized by many physicians, and in areas where the disease is endemic these symptoms are so common and so striking that they have become associated with pellagra even by the lay observer. Various abnormal psychic states have been described in medical literature on pellagra, and some writers have thought that one or another psychosis was typical of this disease.

Subclinical pellagrins are noted for the multiplicity of their complaints, among which are many that are usually classified as neurasthenic. The most common of these symptoms are fatigue, insomnia, anorexia, vertigo, burning sensations in various parts of the body, numbness, palpitation, nervousness, a feeling of unrest and anxiety, headache, forgetfulness, apprehension and distractibility. The conduct of the pellagrins may be normal, but he feels incapable of mental or physical effort, even though he may be ambulatory.

Fig. 2.—Biopsy section of the terminal portion of the internal branch of the normal anterior tibial nerve, stained with fresh 1 per cent osmic acid for from twenty-four to thirty-six hours; X 200. The normal myelin sheaths stain in clear-cut circles.

The noticeable and more serious mental signs of pellagra manifest themselves in various types of psychoses. The most common is perhaps that in which loss of memory, disorientation, confusion and confabulation are predominant. There are also types in which excitement, mania, depression and delirium may occur.

5. Minz, Bruno: Le rôle de la vitamine B₁ dans la régulation humorale du système nerveux, *Presse méd.* 46: 1406-1407 (Sept. 21) 1938.

6. Glick, David, and Antopol, William: The Inhibition of Cholinesterase by Thiamin (Vitamin B₁), *J. Pharmacol. & Exper. Therap.* 65: 389-394 (April) 1939.

In our experience a paranoid condition is common in pellagrins. These patients, acting on their paranoid delusions, are more active than are other pellagrins with psychoses.

The acute psychoses of seventy pellagrins have been relieved quickly with the use of nicotinic acid (Spies, Aring, Gelperin and Bean⁹). The psychosis had been present from one to eighty-three days, and the psychosis of ten patients had been induced in the hospital. From 500 to 1,000 mg. of nicotinic acid was administered daily in 50 mg. doses.

The relief of the numerous and varied abnormal mental signs in this group of pellagrins was dramatic in its suddenness and was maintained as long as nicotinic acid or a well balanced diet supplemented with nicotinic acid was administered. In no instance were we unable to relieve the psychosis. Further experience has upheld the efficacy of nicotinic acid in the treatment of this type of patient.

In thirteen cases we were unable to relieve completely the chronic psychosis accompanying pellagra. Large doses (from 500 to 1,000 mg. daily) of nicotinic acid were administered for periods varying from one and one-half to two and one-half months to the pellagrins suffering from chronic psychoses. These patients became more alert, cooperative and tidy, and apathy and restlessness disappeared. Some of them changed from a bedridden to an ambulatory status. However, hallucinations and delusions usually persisted, although an occasional patient gained some insight into his condition.

Several reports (Evans,⁹ Bogart,¹⁰ Frontali and Ferrari¹¹) have appeared on the beneficial effect of nico-

months, were we able to effect anything approaching complete cure. These cases are too few to serve as a basis for a final opinion.

Nicotinic acid was also administered (Spies, Aring, Gelperin and Bean⁹) to a group of 225 mildly affected pellagrins with complete relief of their rather typical

Fig. 4.—Section of the terminal portion of the internal branch of the anterior tibial nerve of a patient with alcoholic neuritis, ten months after thiamin therapy which had been continuous for two months; $\times 1,000$.

complaints, which have usually been considered to be those of neurasthenia. With nicotinic acid therapy the ambulatory pellagrin also regains energy and appetite. This relief occurs from one to twelve days after the administration of from three to six doses, 100 mg. each, of nicotinic acid a day.

(Nicotinic acid has been reported to have been used with benefit in Wernicke's disease [Jolliffe¹²]. Recent experimental work with animals and clinical observations have indicated that the lack of vitamin B₁ may result in Wernicke's disease and that this condition may be relieved by the administration of vitamin B₁.)

COMMENT

Vitamin B probably has been administered to patients suffering from every kind of nervous disease. Like other new medicaments (insulin, liver extract, sulfanilamide), it has been applied in the treatment of many diseases.

As far as the nervous system is concerned, the evidence suggests the following claims for vitamin B₁ to be allowable: It is of value in correcting and preventing beriberi and the neuritis that accompanies this disease; it is of value in the treatment of the neuritis associated with chronic alcoholism, pellagra and pregnancy. There is enough clinical information available

Fig. 3.—Section of the terminal portion of the internal branch of the anterior tibial nerve of a patient with alcoholic neuritis; $\times 1,225$. There is loss of myelin sheaths. The myelin sheaths remaining are not regular in outline. Wide clefts appear in the substance of the bundles.

tinic acid in the psychosis of pellagra. There has been no report of the complete relief of a chronic pellagrous psychosis of many years' duration. For only one patient, who had been in a mental hospital for nine

at the present time to warrant the trial of thiamin for patients who have peripheral neuritis associated with dietary deficiency or undernutrition from any cause. Also a trial is warranted in peripheral neuritis and edema of undetermined origin.

Our experience with six patients suffering from severe pain (carcinoma, cord tumor, brachial and trigeminal neuralgia) was that thiamin administered intravenously in 50 to 100 mg. doses daily over a period of ten days did not act as an analgesic.

We are unable to evaluate the statements in the literature that other neurologic conditions may be improved with the use of vitamin B₁, but it is our belief that this vitamin is useful in the amelioration of these disorders only if they are caused by its deficiency. It is often difficult to make a clinical diagnosis of vitamin B₁ deficiency with any degree of assurance, but this defect may be remedied shortly by the development of simple diagnostic laboratory methods.

SPECIFIC THERAPEUTIC AND PREVENTIVE MEASURES

The vitamin B deficiencies can be greatly decreased by the application of the following recommendations:

1. Fresh foods, such as potatoes, native vegetables, pork and liver, eggs, milk, fruits and especially beans and whole grain cereals should be substituted for or added to a diet of decorticated cereals and dried or canned foods whenever possible.

2. The use of dried yeast, wheat germ, liver, kidney and vitamin B₁ crystals as supplements to the diet should be encouraged whenever possible. The expense of such materials, however, often interferes with their extensive use.

3. Since vitamin B₁ is water soluble, a large amount of it is lost when the water in which the foods are cooked is thrown away. It is recommended, therefore, that the water in which foods containing vitamin B₁ are cooked be used for broths. Whole barley or other grains which are rich in vitamin B₁ may be added to such broths to insure additional protection.

4. The use of undermilled rather than overmilled grains should be rigidly enforced among government troops and in prisons, asylums and other institutions where mass feeding is required. Each lot of grain purchased should be examined to determine whether there is an adequate amount of the germ and of the external layers of the grain. Since molds, weevils and other infestations deprive cereals of this vitamin, one must be certain that the grain has not spoiled.

5. Particular attention should be directed toward the diets of persons with chronic debilitating diseases and increased metabolism, for the incidence of vitamin B₁ deficiency is high among such patients. Alcoholic addiction, pellagra, sprue, pernicious anemia, colitis, diabetes mellitus, tuberculosis, senility, malignant tumor, cirrhosis and other diseases may interfere with the proper nutrition of the patient and thus predispose to the development of vitamin B₁ deficiency.

6. The diets of pregnant and lactating women should be especially rich in vitamin B₁. Whenever there is any doubt as to the adequacy or utilization of this vitamin either in the mother or in the child, supplements should be given. The supplements should be continued both in the mother and in the child until the proper diet is assured. The nursing mother should receive at least 5 mg. of thiamin or its equivalent daily; the infant

should receive 0.5 mg. a day or its equivalent, and children should receive 1 mg. or its equivalent a day.

7. The requirement for vitamin B₁ may be distinctly above the average in persons with fever, severe gastrointestinal symptoms, hyperthyroidism and other conditions. It is essential for the physician to prescribe amounts above the average for such persons. We suggest a maintenance dose, from 5 to 10 mg. of pure vitamin B₁ or its equivalent a day, except when the patient is unable to absorb from the gastrointestinal tract. In such instances it is essential that vitamin B₁ be given parenterally in order to protect the person from a deficiency of this vitamin.

Our experience leads us to believe that if crystalline vitamin B₁ is to be efficacious in any serious nervous disease it must be given in large doses. We recommend the administration of at least 50 to 100 mg. each day, given parenterally in several doses of from 10 to 20 mg. each. It is also our belief that if no response is obtained within a week, further vitamin B₁ therapy will be unavailing. If these dosages result in improvement of the patient, one may be able to carry him along by the oral administration of thiamin, for a complete cure of these diseases takes a long time. A well rounded diet of 4,500 calories should also be given. This diet must be supplemented with vitamin B or with one or more of the following therapeutic agents: dried brewers' yeast (6 ounces [170 Gm.] daily), wheat germ (6 ounces daily) and extract of rice polishings (tikitiki, 3 ounces [85 Gm.] daily).

SPECIFIC NICOTINIC ACID THERAPY

The dietary advice just noted is as applicable to the pellagrin as to patients suffering from the vitamin B₁ deficiencies.

The optimal dosage of nicotinic acid, like that of thiamin, has not been determined. Neither has the minimal dose of nicotinic acid been determined, but it seems to vary from case to case. It is thought that the pellagrin with severe mental symptoms should receive a total of at least 500 mg. per day. This is best administered by mouth in ten equal doses, although it may be administered parenterally. In the extremely severe cases, convalescence may be shortened by the administration of 1,000 mg. daily. We have given as much as 2,000 mg. daily in divided doses without untoward results. There may be some flushing and feeling of warmth in the skin incident to large doses of nicotinic acid.

ABSTRACT OF DISCUSSION

DR. HANS H. REESE, Madison, Wis.: Drs. Aring, Spies and Evans have given a comprehensive clinical survey on the vitamin B deficiencies, based on the experiences of the Cincinnati group. I challenge only the use of the term "neuritis." Wechsler's recommendation to call this neural deficiency a pathologic condition, neuropathy or polyneuropathy should be accepted. The authors stated: "The experimental evidence available tends to show that vitamin B does not play any direct specific role in counteracting the effects of infectious agents"; then again they say: "It is known that the neuritis in certain persons with infectious diseases disappears following the administration of a well balanced diet." I would like to have explained what is considered a well balanced diet for a person with an infectious disease complicated by neuritis. If forty-five million of our population have to exist at present on an annual income of \$980 and some four and one-half million on an annual income of \$98, it should be made known what a well balanced diet or optimal nutrition for normal physiologic function is which will counteract neuritic complications if members of this group get ill. Furthermore, do

the authors believe that chemical neuritides do not require vitamin B₁, in addition to present-day therapeutic procedures? Since vitamin B₁ is said to be essential for the integrity of the nervous tissue in general, and since its absence may play an important part in the development of neuropathy in a number of nutritional deficiency or metabolic disorders, I would appreciate information as to diagnostic, clinical and laboratory criteria for the assumption of antineuritic B₁ deficiency being present. How is a mild state of pellagra differentiated from a psychoneurotic or psychasthenic state? I cannot do it from the authors' given list of complaints. The section on treatment and general principles of treatment contains such clearly defined, instructive and essential nutritional principles that its contents should be made available to every physician.

DR. J. M. NIELSEN, Los Angeles: In 1932 I had under my care a patient with a severe pellagrinous psychosis. I put him on a high meat diet and in about six months he began to recover his mental capacity. One of his symptoms, which I called a delusion, was that he claimed that his hair was turning black. He had had white hair for about thirty-five years, but after his mental capacity returned he still claimed that his hair was turning black. I examined his scalp and the crown of his head was covered with black hair. Last year I had another patient, aged 86, who had cerebral thromboses and was almost moribund. He took a turn for the better, but his diet had become so deficient that clinical pellagra had developed. I put him on nicotinic acid and nothing else. In a month, black hair was growing on his bald head. About two months ago I put a patient who has no dietary deficiency at all but who had been bald for many years on nicotinic acid, and before I left Los Angeles he had a growth of hair over that bald area about three eighths of an inch long. Now, I should like to ask whether there is any definite experimental or clinical evidence to substantiate the idea that nicotinic acid has some capacity for the production of melanin or darkening, particularly the hair in this area, or whether this is all a coincidence.

DR. GEORGE R. COWGILL, New Haven, Conn.: The question was asked as to the relative importance of protein, fat and carbohydrate, on the one hand, and mineral nutrients, on the other hand, in B₁ avitaminosis. What evidence there is indicates that vitamin B₁ functions primarily in relation to carbohydrate metabolism. About 58 per cent of protein can form sugar in the body. It appears that one should separate the "non-fat calories" from the "fat calories," so to speak, in estimating the human requirement for vitamin B₁. Regarding the minerals, work with the Warburg apparatus in studies of oxidation and reduction involving vitamin B₁ shows that a little manganese in the system is important. There have been some suggestions in the literature that manganese may play some role in the functioning of vitamin B₁ in the body. That is just a suggestion as to how some of these minerals may perhaps come into the picture, although it cannot be said very precisely at the moment how they function. Regarding the quantitative relationship of vitamin B₁ to protein, fat and carbohydrate, I might mention that Dr. Arnold of the University of Wisconsin reported at the recent Toronto meeting of the American Society of Biological Chemists something like 75 micrograms of pure vitamin B₁ as being required for the metabolism of 100 Gm. of protein and carbohydrate; that is to say, the "non-fat calories." That would be a specific contribution in answer to this question. Regarding the effect of cholesterol deficiency, so far as I know cholesterol is not a vitamin. By vitamin I mean a substance which the body needs for its own metabolism and which cannot be made within the organism, hence must be supplied from without. Regarding the man whose gray hair turned black, I might mention that studies have been reported on rats fed a diet lacking the "filtrate factor." When black rats were used for the study and were on the diet lacking the filtrate factor, gray hair developed. When the filtrate factor was later supplied the gray hair became black. Dr. Agnes Fay Morgan of the University of California reported at a recent meeting in Toronto that she had confirmed these observations on brown Boston bull terriers and had produced gray hair in such animals. When the filtrate factor is supplied, the pigment returns. I

don't suppose that such experiments explain the appearance of black hair on a human bald head. I think that is perhaps a little bit beyond us at the moment.

DR. RICHARD M. BRICKNER, New York: I would like to ask the authors whether the use of vitamins has brought out any danger symptoms. Are there any cautions to be given in regard to large doses?

DR. CHARLES D. ARING, Cincinnati: In regard to the therapy of the infectious polyneuritides, one rarely sees a case of infectious polyneuritis since the increased interest in nutrition. One does see the neuritis called "Landry's ascending paralysis," or infective neuritis, or acute infectious polyneuritis. I think it can be stated that no benefit is obtained from vitamin therapy in this disease. In fact, as I noted, progress of neurologic symptoms occurs when the patient is receiving vitamin B₁. Whether or not patients having chemical neuritis improve with B₁ therapy is a moot point. In one case of emetic neuritis in which the dietary had been satisfactory prompt improvement was obtained with intravenous vitamin B₁ therapy. However, other cases of chemical neuritis, such as Jamaica ginger paralysis, of which there were a few fresh cases a year or two ago in Cincinnati, did not respond at all to vitamin B₁ therapy. It would be my advice, therefore, that the vitamin be used in these conditions until more information is obtained. As to what constitutes a well balanced diet, it would take too much time to go into this matter, although, as Dr. Reese points out, it is probably the single most important point in this whole discussion. We have described what we think is a well balanced diet in a paper that is to be published. The differential diagnosis between neurasthenia and mild pellagra is a difficult one clinically. As has been said here, the symptoms are similar. There are, however, certain methods of differentiating these conditions. The finding of porphyrins or similar substances in the urine in cases of mild pellagra and the rapid response of the patient to nicotinic acid, which does not occur in the psychoneurotic patient, would make the diagnosis certain. In the differential diagnosis of nutritional neuritis from other types of neuritis, I think probably the most important point would be the history and the progress of the disease. The mechanical, localized types of neuritis are rather simple of diagnosis. Patients who have been exposed to chemicals and other noxious agents usually give the examiner a lead in the history. There are tests such as the Cline method for determining the excretion of thiamin in the urine, which is a procedure not simple enough to be performed in every physician's office. This method of diagnosis is being developed, and there is likely to be a simple chemical method within the near future. One point that might have a bearing on Dr. Nielsen's patients who have grown black hair after the administration of nicotinic acid: Nicotinic acid improves the local circulation in the head and face. In regard to the dangers of overdosage with thiamin or nicotinic acid, there is practically none. We have given as high as 500 mg. of thiamin a day by mouth, and again 500 mg. of thiamin a day intravenously for weeks. We have administered as much as 2,000 mg. of nicotinic acid a day by mouth without any untoward symptoms.

Mitosis.—The usual mechanism of cell division is the rather complicated process of mitosis, but the cells of some tissues (e. g. cartilage cells under certain conditions) are believed to divide occasionally by the simpler method of amitosis, which involves a direct constriction and splitting of the nucleus without any preliminary anatomical changes in the latter. . . . The whole process of mitosis, as seen in tissue cultures, takes from thirty minutes to two or three hours to complete. The duration of mitosis in the living body has been calculated by indirect methods. It has been shown, for example, by correlating the incidence of mitotic figures with the growth rate of the regenerating liver, that in this tissue each mitosis lasts on the average forty-nine minutes. There is evidence to show that under normal conditions of light, there is a twenty-four hour rhythm in the mitotic division of animal cells, a rhythm which is well known to occur in plants. This periodicity is abolished by continuous exposure to light, but not by continuous darkness. —Clark, W. E. Le Gros: *The Tissues of the Body*, London: Oxford University Press, 1939.

DEPRESSED SKULL FRACTURES; VALUE OF SURGERY; SEQUELAE

AN EIGHT YEAR FOLLOW-UP STUDY OF
NINETY-ONE PATIENTS

MARK ALBERT GLASER, M.D.
AND
FREDERICK P. SHAFER, M.D.
LOS ANGELES

The question of elevation of the depressed fragments in depressed fractures of the skull is one that has been debated for many centuries, and even to this day various opinions are held. It has been assumed that if early elevation is not carried out traumatic cysts, scar formation, adhesions or cerebral softening may occur, which clinically can produce manifestations of psychosis, epilepsy, persistent troublesome and debilitating headache, as well as dizziness.

This series of ninety-one cases has been analyzed for the purpose of determining the disability of the entire group, the sequelae responsible for this disability and the effectiveness of early surgery in the prevention of such symptoms.

This group of ninety-one patients has been divided into five classifications, dependent on the various periods of disability (fig. 1). In group A there are thirty-six patients (39.5 per cent) who were disabled for four months or less. Group B, comprising two patients (2.2 per cent), returned to work at the end of a year. Patients in group C had a permanent partial disability. There were twenty-three patients (25.3 per cent) in this division. Group D was composed of those who were permanently and totally disabled; it consisted of eighteen patients (19.8 per cent). There were twelve patients (13.2 per cent) in group E, all of whom died. Seven of the entire group (7.7 per cent) were women.

This classification indicates that if complaints persist beyond the four months period the opportunity for complete recovery is relatively slight. Approximately 20 per cent of these patients were permanently and totally disabled and 13 per cent died. These results show that, in cases of depressed fracture, permanent disability and mortality are considerably higher than in those cases in which the suffering is from concussion or linear fracture.

In the group of patients who were not unconscious following the original accident or else were only momentarily so affected, all recovered within a period of four months, except two who had brain abscess. In those cases in which there was unconsciousness for from five minutes to twelve hours the difference in time was not associated with any corresponding variation in disability. Thirty-four per cent of the five minute to twelve hour group returned to work within four months, whereas about 54 per cent went on to some form of disability; approximately 11 per cent died. In the twelve to forty-eight hour group 44 per cent died, and a similar proportion went on to partial or total permanent disability. Among those who were unconscious for from two to seven days, about 65 per cent developed permanent disability. It is apparent that the period of unconsciousness is definitely related to disability, and the longer the patient has been unconscious the more

chance there is of some form of disability developing. If the patient is not unconscious at all his chances for recovery are extremely good, though there is little difference whether a patient is unconscious for five minutes or for twelve hours. Of the total group of ninety-one patients, 13 per cent were not rendered unconscious following the accident and 9 per cent were only momentarily so affected; 48 per cent suffered from loss of consciousness for from five minutes to twelve hours, 10 per cent from twelve to forty-eight hours and 19 per cent from two to seven days (fig. 5).

As has been previously stated, the purpose of early elevation of depressed fractures has been to prevent development of late symptoms. In this series of cases a correlation of figures 6 and 7 will indicate the results of operative intervention obtained in these cases. In group A, thirty-six patients (39.5 per cent) of the entire series) returned to work within a period of four months or less and have been entirely symptom free up to the present time; twenty-three patients (63.9 per cent) were operated on and thirteen patients (36.1 per cent) were not. This clearly demonstrates that the performance of surgery was not a factor in preventing sequelae, as approximately one third of these patients got along perfectly well without operative intervention. In group B there were two patients (2.2 per cent) of the series; neither was operated on, but they continued to complain of mild headaches and dizziness for a period

Fig. 1.—Depressed fractures in relation to disability.

of one year. These subjective symptoms then subsided and they were returned to a normal wage earning basis. It is quite evident from these facts that in this group of patients, if complete recovery did not occur within a period of four months, the probability of some form of permanent disability was relatively great. In group C there were twenty-three patients, of whom nineteen, or 82.6 per cent, were operated on. In spite of the fact that the depressions were elevated, these patients developed partial permanent disability. In group D there were eighteen patients, of whom 83.3 per cent were operated on; nevertheless they had total permanent disability. Referring to figure 7, the sequelae may be observed in detail. In addition to these sequelae, the patients complained to a lesser degree of fatigue, insomnia, tinnitus, body pains, transient numbness, staggering gait, anorexia and loss of libido. In group C convulsions occurred in 34.8 per cent of the patients, and in group D in 38.9 per cent. However, in group D extreme psychoses accounted for the disability in 72.2 per cent of the cases, whereas neurologic signs were a minor factor. Subjective complaints of headache, dizziness and nervousness were present in the neighborhood of 50 per cent in both C and D groups but were not necessarily of a disabling nature. All these sequelae except convulsions developed immediately after injury; the psychoses, eliminating the acute psychotic state, of the early part of the injury, showed variations in degree from time to time, while the nervousness frequently increased. The convulsions and psychoses occurred in a much higher proportion than in the series of general

head injuries.²⁶ The sequelae in the entire series, groups A, B, C and D, were as follows: headaches 44.3 per cent, dizziness 30.3 per cent, nervousness 27.8 per cent, convulsions 19 per cent, extreme psychoses 16.4 per cent, involvement of the eighth nerve 13.9 per cent, mild psychoses 10.1 per cent, hemiparesis 8.9 per cent,

thirteen (31.7 per cent), postconcussion syndrome, aggravated by a mild neurosis in some instances, ten (24.8 per cent), neurologic signs consisting of blindness in three instances and paresis in one (9.8 per cent), and a severe post-traumatic neurosis in three (7.3 per cent).

The development of a post-traumatic neurosis must not be overlooked in cases of head injury. This may be caused by maladjustments in the emotional realm, financial difficulties, family troubles, antagonism to physician or insurance carrier and dissatisfaction of various and sundry forms.²⁷ From the industrial standpoint, as well as for the good of the patient, when a post-traumatic neurosis develops and constitutes the main disabling factor present its early recognition is paramount. The cause of the condition must be ascertained and adjusted if possible. Medical care itself is of little avail when finances or antagonism are responsible. In such instances a financial settlement is the best means of solving the problem.

Convulsions occurred in fifteen cases, which is 16 per cent of the entire series. This is a very high percentage of convulsive states following brain trauma as compared to 3.3 per cent reported by us²⁸ previously in general head injuries. This indicates that depressed skull fractures are exceptionally prone to convulsive states.

Post-traumatic psychosis occurred in thirteen cases to a severe degree and in six cases to a mild degree. In the psychoses there was a complete reversal of personality associated with unreasonable attitude, irresponsibility, unreliability, periodic tantrums or mania. The patients were emotionally unstable, morose, restless

and unable to adapt themselves to their former occupations. Occasionally this became so severe that they were necessarily confined to a sanatorium. Memory and judgment were often impaired, and restlessness and confusion or moodiness existed.

The abnormalities found on vestibular tests have previously been reported.²⁹

SEQUELAE

It is very evident that early elevation did not prevent the development of sequelae in this series; this corresponds to an experimental observation reported by Naffziger and Glaser in 1930.³⁰ These experiments indicated that the force of the blow struck was responsible for the underlying damage to the brain in simple depressed fractures, and the pathologic condition was not due to a rounded depression of bone pressing on the brain. Elevation should be confined to fractures of a fragmented and spiculated nature wherein the dura has been perforated and the brain traumatized or when the depression is over functioning cortical areas. It is very difficult to lay down a hard and fast rule as to the type of case which does not require elevation, because frequently even by careful radiologic examination we are unable to judge when the dura has been lacerated and the underlying cortex injured. Each case is a problem in itself and requires the personal

judgment of the surgeon. Immediate elevation is definitely unimportant (figs. 12 and 14). Shock, intracranial pressure, hemorrhage and associated injuries must be considered first. Only when a patient is in good condition is the operation indicated, and it should never be performed without an x-ray examination. The final objective in the operative treatment of a depressed fracture is to renew the depression and repair the cranial defect. When infection is not present the fragments of bone may be replaced. In cases in which a possibility of infection exists, or when the patient has been seen several days after the injury or it is necessary to delay surgery several days, primary wound suture may be carried out as the only immediate operation; then at a later date the depression may be elevated and the bony fragments utilized for repair of the skull. By this means a sterile field is insured for the secondary operation.

The surgeon who favors early elevation in all cases of depressed fracture because he believes that this will prevent the onset of sequelae and is of the opinion that sequelae may be caused by the pressure of bone on the brain should similarly believe that elevation of late fractures is indicated in all instances. This argument could be supported by the theory that continued pressure of bone on the brain will cause further damage and consequently elevation should be carried out at any time with or without symptoms. However, our clinical and experimental data do not justify such conclusions. For this reason we do not favor the early elevation of all depressed fractures, and we definitely do not believe that symptom-free late depressed fractures should be operated on in any instance; further, we

Fig. 9.—Encephalogram of patient with convulsions due to a cyst. Note ventricular changes, cyst and bone defects.

believe that exploration should not be done in cases of cranial defect of long standing and without symptoms for the purpose of preventing later cerebral complaints.

In cases presenting symptoms seen at a late date in which the depression is not elevated, it must be determined whether the symptoms are to be attributed to the injury. In those presenting a post-traumatic neurosis no surgery of any type is performed. In cases of a postconcussion syndrome, with predominating head-

aches and dizziness, the question of encephalography is seriously contemplated, as it must be remembered that this procedure in many instances relieves the headaches and dizziness.³¹ Post-traumatic epilepsy always begins at a late date, and each patient should have an encephalogram performed. Encephalography, plus the use of sedatives in a number of instances, in our

Fig. 10.—Patient with birth injury twenty-four years before suddenly had convulsions. The depressed area is still apparent and the ventricles are dilated, unequal and shifted; cortical air is absent.

series has relieved convulsions, whereas previous to the encephalogram sedatives were not effective. Depending on the encephalographic diagnosis of cysts, adhesions, ventricular distortion or shifts, surgery may or may not be carried out.³² Little or nothing can be accomplished in the line of surgery for the post-traumatic psychosis. However, an encephalogram will give added information as to the underlying cerebral pathologic condition causing these mental changes. The same type of medical conduct is followed in cases of cranial defects plus symptoms, as in cases in which the bone has not been elevated.

PROCEDURES

A number of methods have been advocated for elevating and removing the depressed portion of bone. In the majority of instances the fragments are badly shattered, depressed and impacted, so that it is quite easy to start the removal of bone by lifting out a single piece, with the aid of a rongeur or elevator. Occasionally it may be necessary to start the elevation by the use of a perforator. All depressed fragments should be removed and the edges of the fracture carefully

inspected to make certain that any spicules which may have penetrated the dura and injured the brain are not left in situ. By this method the entire underlying dura may be properly inspected and the fragments utilized in the restoration of the skull. The application of a catgut screen for bone replacement will be considered in detail later. The use of an elevator alone,

Fig. 12.—Same patient as in figure 11 two years later; note the difference in the depressed portion.

introduced through a small opening with a prying up of the fragments, does not permit inspection of the dura and for this reason is not advisable. It has been suggested that in small depressions a trephine be utilized to remove the entire fragment. The button of bone thus separated may be replaced, thereby elevating the fracture and restoring the bone in one procedure. This method is applicable in only a few instances but proves quite effective when it can be used. In certain instances of compound fracture it has been advised that the area of depression be resected, leaving a wide margin around the broken bone so as to prevent infection of the underlying brain and maintain a sterile field. Since the whole wound is potentially infected in such instances, it is questionable whether asepsis can be maintained. The turning down of a bone flap around the area of depression with the hammering out of the central depressed fragments and replacement of the flap is quite a formidable procedure when restoration can be obtained with more simple means. In addition, the whole principle is defeated should the central bony fragments break away from the bone flap.

The surgery of the dura may be divided into two parts: first, the question of opening the dura when it has not been lacerated and, second, the repair of the dura when it has been lacerated. Peet² is of the opinion that the dura should be opened and the underlying brain inspected. It is his belief that the existence of traumatized or devitalized brain has a destructive action on the adjacent normal brain, and by the removal of the devitalized brain tissue the normal brain is protected from further danger and a vicious circle is pre-

vented; softening does not occur, with the result that the brain injury is materially reduced. Gross, Furlow and Sachs do not favor the opening of an uninjured dura. In our own cases we did not open the dura to inspect the underlying brain except when there seemed some probability that hemorrhage or increased pressure was present.

In cases in which the dura was lacerated the traumatized edges were trimmed, and when the dura could be sutured this procedure was carried out. In cases in which the dura cannot be approximated, the question of a dural graft must be considered. Various reasons have been advocated for the use of grafts, and this question at the present time is one of surgical debate. It is believed by some that a dural graft is entirely unnecessary and at times may even be harmful because of a foreign body reaction, which would aid the formation of excessive adhesions. Those who favor the dural graft believe that it is valuable because it prevents the rough edges of the bone from irritating the underlying brain, thus obviating the formation of surface adhesions; also it forms a water-tight closure of the brain and hence opposes the entrance of infection; it hinders or makes impossible the production of a brain fungus should the intracranial pressure rise from any cause, and, finally, since it makes a definite layer over the surface of the brain so as to permit the insertion of bone fragments.³³

Experimental studies carried out indicate that the use of a graft just to close the dura is entirely unnecessary since the dura will repair itself, the new cells arising from the edges of the dura and from the overlying fascia and muscle. Should it be necessary to insert a graft, animal membrane has proved just as efficient as an autoplasmic graft taken from the fascia lata or the temporal fascia. Further, it has been demonstrated that the heteroplastic graft of animal membrane is entirely absorbed within twelve months, both experimentally and clinically. The use of a dural graft is entirely dependent in each individual case and when utilized is efficient and harmless. All devitalized brain should be removed by dissection and suction, and deeply embedded bone should be extirpated.

It is best to repair the cranial defect immediately at the time of elevation, if this is possible. In wounds

Fig. 13.—Weaving board with catgut woven into a screen.

33. Glaser, M. A., and Thielen, C. H.: Dural Defects: How Important Is Their Surgical Repair? *California & West. Med.* 49:463 (March) 1938.

of a compound nature which are potentially infected, primary suture may facilitate a healing of the wound so that the fragments may be utilized at a later date. The small pieces of bone can be fitted into a mosaic pattern and the entire defect closed. Frequently it is difficult to replace all the fragments of bone and completely cover the defect. It is necessary for all the

Fig. 14.—Particles of bone inserted at time of operation. Note the filling in of defect.

space to be filled with either small particles of bone or bone dust so as to obtain a complete fill of the defect. In order to keep the small fragments in place, a catgut screen may be woven, the catgut sterilized and sutured to the periosteum over the small fragments, thus keeping them in place while the scalp is sutured (fig. 13). This promotes complete ossification of the defect (fig. 14). Cranial defects never fill in, the aperture never grows smaller and the only change that occurs is a smoothing of the sharp borders around the edges of the bone (no infants in series).³⁴ These defects are closed for cosmetic purposes, as a matter of protection, to remove the psychic effect associated by this absent bone and to prevent the pressure sensations and early morning bulging, as well as the feeling of cerebral pulsation. The employment of artificial substitutes, such as silver, vulcanite, aluminum, ivory, celluloid and rubber, has been advocated by Elsberg Mitchell, Erdheim and Pringle.³⁵ The use of heterogenous bone from animals, birds or autopsy material has been suggested by Babcock and Pankratiev. Homoplastic transplants have been taken from the tibia, rib, scapula, ilium and the like (Bagley Breninger, Jones, McWilliams, Primrose, Rhodes, Lexer, Dambrin, Juvara). However, it is the general consensus that osteoperiosteal grafts taken from the adjoining area of the skull are easy to obtain and the results are excellent (Wagner, Frazier, Coleman, Gurdjian, Peet).

In our own series, the osteoperiosteal graft has proved unusually satisfactory. Roentgenograms taken a short time after the graft has been placed reveal the absence

of calcium deposit within the graft. However, at a later date islands of bone will become visible, and finally the entire defect gradually becomes smaller, filling in from the edges (fig. 15 and 16). On palpation this area is firm and solid to the touch.

CONCLUSIONS

1. Surgery does not always prevent the development of sequelae because of the existing brain damage associated with the depressed bone.

2. Recovery from depressed fractures occurs without operation in properly selected cases.

3. The sequelae that develop are convulsions, psychoses, headaches, dizziness, nervousness, aphasia, hemiparesis and involvement of the first, second, third, fourth, sixth and eighth cranial nerves.

4. If the patient does not return to work within the first four months, the probability of partial or total permanent disability developing is great.

5. In simple depressed fractures clinical and experimental evidence indicate that the pathologic condition is caused by the original blow struck and not by any irritation of the overlying depressed portion of bone.

6. Injuries resulting from automobile accidents were the most severe; fractures were more frequent in the frontal and parietal bones; fractures in the young and the old were the most serious; 7.7 per cent of the cases were in women.

7. Patients who were not rendered unconscious recovered within four months; those who were unconscious for from five to twelve hours developed approximately the same disability; but, after the twelve hour period, the longer they were unconscious, the greater was the final disability.

8. Early elevation should be confined to fractures of a fragmented or spiculated nature wherein the dura

Fig. 16.—Osteoperiosteal graft inserted. Note closure of the defect three years later.

has been perforated or when the depression is over functioning cortical areas. No hard and fast rule can be laid down for the type of depression to elevate, but, bearing the principles in mind that simple depressions are not harmful, the penetration of the dura cannot always be determined by x-ray examination; personal judgment is essential. Operation should carry no mortality.

34. Glaser, M. A., and Blaine, E. S.: Duration of Fractures and Operative Defects of the Skull (As Revealed by Roentgenograms), *J. A. M. A.* 107: 21-24 (July 4) 1936.
35. Pringle, J. H.: Treatment of Acquired Defects of the Skull, *Brit. M. J.* 2: 1105-1107 (Dec. 4) 1937.

9. A badly lacerated wound may be converted into a closed wound by primary suture to conserve the underlying bone and delay early formidable surgery.

10. Patients with late depressed fractures or cranial defects without symptoms should not be operated on.

11. Patients with late depressed fractures or cranial defects, with certain symptoms, should have encephalograms performed and surgery if necessary.

12. Cranial defects never heal spontaneously (no infants in series). At the time of elevation, the use of a catgut screen to hold small fragments of bone in place insures complete ossification of the defect. Late defects are best treated by an osteoperiosteal graft.

ABSTRACT OF DISCUSSION

DR. JOHN H. POWERS, Cooperstown, N. Y.: A number of depressed fractures of the skull are seen in a rural area due almost entirely to the automobile or a kick in the head by an animal. Some of these are exceedingly severe, and three were responsible for deaths in my series of farm accidents. In a rather limited experience I have relied on certain rules in the treatment of depressed fractures of the skull. I feel that any depressed fracture involving both the outer and inner tables overlying the motor area, in which there is even a suspicion of pressure on the dura, should be explored and the fragments elevated. These patients later on are prone to develop sequelae from such depressed fractures over the motor center. Furthermore, I think that every compound fracture of the skull, whether depressed or not, should be operated on, the edges of the wound being extensively debrided and if possible approximated thereafter. If it is impossible to close the wound, it must be allowed to granulate. I was not quite clear as to the relationship of the sequelae, particularly convulsions, in patients operated on and those not operated on. I was particularly interested in the authors' description of the method of treating defects in the skull. I feel that a small defect is of no significance. I am under the impression that in children such small defects may decrease in size over a period of years.

DR. MARK A. GLASER, Los Angeles: In reference to the elevation of a simple nonspiculated depressed fracture of the skull certain fundamental principles must be borne in mind. First, the experimental work has indicated that the blow struck is responsible for the underlying pathologic condition, and not the rounded depression of bone. Second, sequelae developed in 83 per cent of the cases in which operation was performed. While in group A sequelae developed in only 38 per cent of the cases, no operation was performed. From these experimental and clinical results it is evident that fundamentally it is the blow that causes the damage and not the rounded depression of bone and further surgery does not necessarily prevent sequelae. In cases of simple rounded depressed fractures without spiculation or fragmentation of the inner table which would indicate penetration of the dura and over nonfunctional cortical areas we do not favor elevation. Frequently in compound fractures the original wound is sutured and at a later date the bone is handled. In this manner the skull may be conserved without any danger of infection and the fragments replaced so as to prevent a cranial defect. In certain cases in which the question of elevation is a matter of doubt it is always best to carry out the procedure and in all instances the personal judgment of the surgeon in charge is all important. In children when the bones of the skull have become calcified the aperture of the cranial defect does not decrease in size. This has been previously reported by Dr. Blaine and myself. It is true that in children linear fractures may disappear within six months or so whereas in adults they have been found visible as long as seven years later. However, in some instances they have disappeared in eighteen months. The primary treatment of depressed fractures is to consider the brain damage, and the secondary treatment is to restore the skull. When the defects are seen at a late date it is frequently necessary to repair the skull because of the fear of the patients and the subjective symptoms that occur with this defect. In my experience an osteoplastic flap is most satisfactory.

THE REACTION OF THE CORONARY VESSELS TO DRUGS AND OTHER SUBSTANCES

LOUIS N. KATZ, M.D.

AND

ERNA LINDNER, B.S.

CHICAGO

A great deal of confusion exists concerning the reactions of the coronary blood vessels to many products of metabolic origin and to numerous drugs. The prevailing contradictions regarding the reaction of the coronary vessels arise from the circumstances under which the measurements have been made, the indirectness of the methods used in some studies and the abnormality of the conditions in others. We have become concerned with this problem and have developed a method by which the action of various drugs and other substances directly on the smooth muscle of the coronary vessels can be determined without at the same time being altered by the other factors which indirectly affect the rate of coronary flow. Our method, which employs a normal denervated dog's coronary vessels perfused in situ with defibrinated dog's blood, permits a direct determination of whether a substance has a vasodilator or a vasoconstrictor action on the coronary vessels.

It must be emphasized that besides its effect in actively altering the caliber of coronary vessels a drug may also passively change the coronary caliber by its other actions. Hence coronary vasodilatation and coronary vasoconstriction are not necessarily accompanied by the expected changes in coronary flow in the intact animal and in man. Further, for practical purposes the important thing is not whether the substance has a coronary vasodilator or vasoconstrictor action nor whether the substance increases coronary flow or decreases it but rather how it influences the relation of the change in coronary flow to the alteration in the work of the heart and to the energy cost on the part of the heart in doing this work. A drug that dilates the coronary vessels actively and that increases the coronary flow may still be valueless or even harmful if it has a disproportionately greater augmenting action on the energy cost and work of the heart. It is the change in the ratio of coronary caliber and coronary flow to the work and energy expenditure of the heart that is the important criterion in determining the value of a drug. To evaluate the merit of a drug properly a knowledge of its action (1) on the active coronary caliber changes, (2) on the total coronary flow and (3) on the work and energy expenditure of the heart is necessary. In this report we deal with our results on the first of these factors. Studies are now in progress to determine the effects on the other two.

The passive factors controlling coronary caliber play an important role in determining coronary flow. For example, the pressure fluctuations in the aorta are of prime importance. In estimating their effects it is not enough to know just the mean pressure but also the cyclic alterations between the systolic and diastolic pressures. Likewise we have shown that the pressures existing in the cavities of the heart and the tension developed within the walls of the heart chambers pro-

and of the National Research Council.

foundly alter the coronary flow.¹ Drugs may produce their action on coronary flow indirectly by affecting these factors rather than by a direct action on the smooth muscles of the coronary vessels, or these side actions may counterbalance the direct action.

Another serious error in measuring coronary flow is the use of the coronary sinus drainage as an index of coronary vasoconstriction or vasodilatation. The coronary sinus is only one of the drainage channels of the coronary system, the others being the thebesian veins, which empty directly into the heart cavities, chiefly on the right side. We have shown² that the coronary sinus flow is a variable proportion of the total coronary flow and that therefore it is not a reliable measure of coronary vasoconstriction and vasodilatation. Coronary sinus flow changes may represent alterations in the partition of coronary drainage between it and the thebesian channels rather than the changes in total coronary flow. An idea of the complexities of the factors governing coronary flow may be obtained from the accompanying diagram.

We have recently developed a method of perfusing the dog's coronary system³ in which the perfusion pressure was maintained constant (at about 120 mm. of mercury) throughout the experiment and in which the intramyocardial tensions and intracardiac pressures were kept constant (at atmospheric pressure) by throwing the ventricles and auricles into fibrillation and keeping the heart cavities open to the outside. We have shown that the incoordinate action of fibrillation is without effect on coronary flow when the heart chambers are open to atmosphere.⁴ The coronary flow in our studies was determined by measuring either the total inflow into the coronary arteries or the total coronary outflow leaving the pulmonary artery. In the latter case the error involved in ignoring the thebesian flow into the left heart is negligible.² In this preparation, therefore, a decrease or increase in coronary flow, as measured, can result only from an active decrease or increase,

Epinephrine⁵ in all doses used caused the coronaries to dilate, indicating an active diminution in coronary vascular tone. On occasion, transient constriction preceded the dilatation. Ergotamine tartrate occasionally caused constriction but had no effect on the coronary dilatory reaction to epinephrine. The dioxane derivative 933 F, piperodimethylbenzodioxane, a synthetic compound pharmacologically similar to ergotamine in

The variable factors determining the coronary flow. Chamber *A* represents the variable pressure head in the aorta. Chamber *H. W.* represents the variable tension within the walls of the heart; the small coronary vessels (*COR.*) are represented as being partly out of this chamber, since intramyocardial tension is variable in different heart chambers and across the thickness of the heart wall. *C. A.* represents the three major coronary arteries which lie partly in and partly outside the myocardium. *SIN.* and *TH.* represent the drainage channels; the former is the coronary sinus, the latter the thebesian channels. They are shown to empty into chambers *R. A.* and *R. V.*, the right auricle and ventricle respectively; both of these are represented as variable pressure chambers. (For simplicity, the drainage up to 10 per cent by the thebesian channels into the left heart and the considerable thebesian drainage into the right auricle are not shown.) The smooth muscle of the coronary vessels, which represents the site where active vasodilatation and vasoconstriction occur, is indicated by the thickenings *M. W.* *L* represents the pulmonary circuit.

Coronary Vasodilator and Vasoconstrictor Drugs and Substances Based on Observations on the Isolated Fibrillating Dog Heart

Coronary Vasodilator Drugs and Substances

Epinephrine (at times preceded by mild transitory adrenergic constriction)
Acetylcholine derivatives (cholinergic)
Calcium chloride
Sodium chloride
Potassium chloride (when less than 1½ of normal blood concentration)
Glyceryl trinitrate and sodium nitrite
Histamine
Caffeine, aminophylline and other xanthines
Diffusible substances liberated in myocardial ischemia

Coronary Vasoconstrictor Drugs and Substances

Ergotamine (only at times)
Piperodimethylbenzodioxane
Potassium chloride (when greater than 1½ of normal blood concentration)
Pitresin
Atropine sulfate (mild)
Substance in defibrinated foreign species blood

respectively, in the caliber of the coronary vessel, i. e. vasoconstriction and vasodilatation.

Using this method, we have studied the action of a variety of drugs, salts, bloods of foreign species and temporary coronary ischemia on the tone of the coronary vessels of the dog. The principal effects discussed in this report are summarized in the table.

that it inhibits sympathetic vasoconstriction, produced an increase in coronary tone and abolished the preliminary constriction caused by epinephrine, leaving the dilator response of epinephrine unaltered. The increase in coronary flow, definitely established to occur in the normal unanesthetized dog,⁵ is probably due to a large extent to this active coronary vasodilatation. Assuming, on the basis of experimental evidence, that the dog is closely representative of the human being in this regard, it would appear that coronary dilatation is the more usual response to epinephrine in man. When constriction does occur, it is probably only a mild preliminary to a more marked and persistent dilatation.

Dilatation was the only effect noted with all doses of either acetylcholine or mecholyl (acetyl-β-methylcholine).³ The degree of dilatation was dependent on the strength of the dose. Ergotamine and piperodimethylbenzodioxane had no effect on the action of these two drugs. Atropine, however, completely abolished or diminished these responses. Physostigmine, known to accentuate acetylcholine vascular responses elsewhere, antagonized this inhibitory action of atropine. Thus it appears that the initial constricting action of epinephrine and the persistent dilating action of the choline derivatives on the dog's coronary vessels are correspondingly adrenergic and cholinergic, since they are abolished by piperodimethylbenzodioxane and atropine, respectively. This is in accord with our studies on the innervation of the coronary vessels,⁶ in

which, contrary to many investigators, we obtained in this preparation only dilator effects from stimulation of the vagi and both dilator and constrictor effects from stimulation of the sympathetic nerves.

Glyceryl trinitrate (nitroglycerin), sodium nitrite, histamine and caffeine caused marked and persistent coronary dilatation. Some of the other xanthine derivatives (aminophylline, theophylline and the like) produced a similar but weaker effect.³ On the other hand, pitressin caused a very powerful constriction, which continued for a half an hour or more without appreciably lessening in degree.³ Our results on digitalis are as yet incomplete but they show that in large doses approaching the toxic level a constricting action occurs.

Sodium and calcium chloride produce definite dilatation, the latter giving a more pronounced and longer lasting effect.⁴ Potassium chloride had a variable action depending on the concentration used.⁴ Thus, doses up to one and two-thirds times the amount normally found in defibrinated dog blood produced dilatation, whereas doses from one and one-half to two and one-half times the normal concentration produced constriction, at times almost to the point of complete closure. In view of the fact that the potassium content of the blood has been found⁷ to increase from 50 to 100 per cent in the circulatory collapse produced by hemorrhage, shock and adrenal cortical insufficiency, it is not improbable that the excess of potassium contributes in these conditions to the circulatory failure by its constricting action on the coronary vessels.

Defibrinated whole blood of sheep, beef and pig caused a marked coronary constriction.⁸ This reaction must be due to a coronary constrictor substance in the blood of a foreign species and not, as has been suggested, to histamine, which in the dog causes coronary dilatation.³ There was a superficial resemblance to an anaphylactoid reaction in that the coronary vessels of the intact animal could be desensitized to this substance by preliminary repeated injections of the same blood in increasing amounts.

We have confirmed the fact that cardiac ischemia leads to a reactive hyperemia in that temporary stoppage of the coronary flow is followed by a noticeable coronary dilatation.⁹ The dilatation appears to be due to the destruction of nondiffusible substances or to the accumulation of diffusible metabolites which normally are either nondiffusible or in some way destroyed or modified when oxygen is present. These effects of temporary coronary occlusion suggest that there exists in the heart an efficient mechanism which, by producing coronary dilatation, operates to maintain this organ in a normal state by increasing its blood supply whenever myocardial needs are not met by the existing coronary flow. Such a lack of balance between myocardial needs and coronary blood supply can occur under any one or any combination of the following circumstances: (1) when the blood supplying the heart is of poor quality, (2) when cardiac work suddenly increases out of proportion to coronary flow augmentation, and (3) when there is a primary inadequacy of coronary flow, the result of coronary narrowing or occlusion.

Since the heart is extraordinarily susceptible to relative anoxemia and ischemia¹⁰ and, further, cannot

pause for long periods in order to recover from handicaps as can other organs of the body, reactive hyperemia must be viewed as a very important mechanism for maintaining cardiac function. Interestingly, cardiac ischemia, while leading to coronary dilatation, in man often also results in angina pectoris. Because of his pain, the patient is compelled to slacken his activities and hence reduce the work demanded of his heart, thereby tending to bring into closer balance his myocardial needs and blood supply. It is quite probable that coronary vasomotor reflexes and humoral mechanisms may be brought into play to assist this local dilatatory compensatory mechanism, but our knowledge concerning this is still far from complete.

The occurrence of powerful constriction in the coronary vessels following ergotamine, piperidomethylbenzodioxane and especially potassium, pitressin and the blood of foreign species suggests the possibility that coronary spasm can and may occur in man. Our results further suggest that under such circumstances calcium may prove of real therapeutic value by decreasing the tone of the coronary arteries. We make the latter suggestion advisedly, however, for, in spite of the consistency with which calcium chloride increased coronary flow in our experiments, this salt is known to augment the strength of the heart beat and also to render the heart, especially when it is depressed, hyperirritable, and thus may lead to ectopic rhythms. Obviously, before calcium can be used therapeutically with safety, evidence must be procured which establishes that its enhancement of cardiac activity is more than compensated for by its coronary vascular action, and the conditions under which its administration becomes hazardous must be more clearly defined.

Following along the line of thought of improving the balance between the work of the heart and the coronary circulation, a few comments regarding the action of epinephrine are pertinent. In spite of the evidence pointing toward improvement of coronary flow, presumably due in large part to active coronary dilatation, angina pectoris in man is known to be precipitated by this drug. It is quite possible that such attacks are the result of a disproportionately greater increase in the work and energy consumption of the heart than in the coronary flow. Coronary sclerosis would, of course, make the disbalance between coronary flow and cardiac work more pronounced.

The analytic method of studying the action of drugs which our experiments exemplify is essential in clarifying the synthetized action of drugs on the various activities of the heart and the circulation in the intact animal. It is vital to rational treatment, but data obtained from such studies must be carefully integrated with the other actions of the drug before the results can be applied in man. This is particularly the case with so-called coronary drugs.

Twenty-Ninth Street and Ellis Avenue.

ABSTRACT OF DISCUSSION

DR. FRED M. SMITH, Iowa City: I wish to refer to the action of the nitrites and the purine base derivatives and their use in the treatment of coronary artery disease. Even in extensive arteriosclerosis of the coronary arteries the process concerns for the most part the larger vessels, and the smaller arteries, especially the arterioles, are generally remarkably free from involvement. Thus the arterioles and the capillaries are usually intact and capable of responding to the action of the vasodilator drugs. There does not seem to be any doubt regarding the vasodilating action of the nitrites on the coronary arteries. The results from experimental studies are generally

accepted, and moreover dramatic effects are commonly observed from the use of glyceryl trinitrate and amyl nitrite in the treatment of attacks of angina pectoris. It is believed, however, that the effectiveness of these preparations may be increased if given more often. I usually prescribe glyceryl trinitrate and direct that it be taken three or four times a day in addition to the amount necessary to control attacks, with the idea of possibly promoting the development of collateral circulation. However, one should test out the action of these drugs on the individual. There has been considerable doubt regarding the action of the purine base derivatives. At the present time, however, the evidence is overwhelmingly in favor of a dilating action on the coronary arteries. Furthermore, the clinical results are in general accord with this concept. A fairly good percentage of patients with angina pectoris will derive benefit from these preparations if given in adequate doses. The results, however, are far more striking if a preparation such as aminophyllin is administered intravenously. Dramatic results are commonly observed in the treatment of acute ventricular failure on the left side. Moreover, the pain of acute coronary thrombosis may be abolished by this form of medication.

DR. GEORGE V. LEROY, Chicago: What interested me most was the effect the authors obtained with different drugs on coronary flow and the fact that these results were obtained in denervated, isolated, fibrillating hearts. It has always seemed to me that the denervated, isolated, fibrillating heart does not exactly represent the situation that confronts the therapist. He wishes, if possible, to alter the circulation in the coronary arteries to improve the blood flow in terms of a given demand. My experiments have been performed by means of the Morawitz cannula, which the authors do not approve so highly, and, surprisingly, the results are very comparable with theirs. I questioned the validity of experiments even with the cannula, because the dog was under an anesthetic, so I constructed a Rein thermostromuhr, and my experiments with it have paralleled those of Dr. Essex. Using several of the drugs which the authors mentioned, specifically epinephrine and amphetamine, which is related to it, acetylcholine, pitressin, the purine base diuretics and glyceryl trinitrate, I found the variations of the coronary flow to have been in the same direction as when other methods were used. The finding of the same magnitude and direction of flow changes with different methods: with the isolated, fibrillating heart, perfused under constant pressure, the finding of the change of the same magnitude with the Morawitz cannula in the coronary sinus and the finding of the same change in magnitude with the Rein thermostromuhr on a coronary artery of a conscious dog that walks into the laboratory and receives the injection suggest that criticism of any of the three methods in terms of the other is not justified. One point which has interested me was the effect of pitressin. The reduction of flow that the authors found is similar in extent to what I ordinarily find in my preparations, either with the thermostromuhr or with the Morawitz cannula. This restriction in flow may be abolished very promptly by the administration of some of the xanthines. A dose of aminophyllin or theobromine relaxes it completely and the flow comes back to normal. The same is true of amphetamine and epinephrine. It appears that the effect of pitressin is a transitory affair which can be eliminated.

DR. GEORGE K. FENN, Chicago: Dr. Smith called attention to the uniformly good results in the matter of coronary dilation with the purine base diuretics. Our work, in which Dr. LeRoy participated and which was done largely by him, drew pitressin to my attention. Pitressin, measured both by the Morawitz cannula and by the Rein thermostromuhr, caused a tremendous decrease in coronary flow, which we assumed was on the basis of coronary constriction. Because of the widespread use of pitressin as a postoperative medication, we thought that attention might well be drawn to its clinical possibilities. I would hesitate to give a patient who had any sign of coronary disease any considerable amount of pitressin. The same might be said about the potassium salts so often given in shock.

DR. ERWIN E. NELSON, New Orleans: I should like to ask Dr. Katz a question with respect to the action of pitressin versus solution of posterior pituitary. In the laboratory I usually find that pitressin is a great deal more toxic than the equivalent amount of solution of posterior pituitary.

DR. LOUIS N. KATZ, Chicago: We have had no experience with the preparations of solution of posterior pituitary of which Dr. Nelson speaks. I am pleased to know that the results reported by Dr. LeRoy on unanesthetized animals with the Rein thermostromuhr are in accord with data obtained in anesthetized animals with the Morawitz cannula and with the data presented by us on the isolated heart preparation. However, it seems to me that it is hazardous to conclude that the mode of action is identical in the three cases. As we stated in our report, in the intact animal other factors besides active change in the tone of the musculature of the coronary vessels contribute to determine the coronary flow. It is unwarranted, therefore, to attribute all such changes in flow to active coronary dilatation or constriction. Only when the role of the passive factors is eliminated or discounted can that deduction be made. For example, histamine decreases coronary vessel tone, as we have shown; yet when it is given to the intact animal or to man the profound drop in blood pressure may counteract this direct coronary action and decrease coronary flow. Again, epinephrine actively dilates the coronary vessels, and this is apparent in the intact animal; yet when given to patients with coronary sclerosis and angina pectoris it will in many instances precipitate an anginal attack because it increases the work of the heart more than it increases coronary flow. I agree with Dr. Fenn that our results point to a hazard in the clinical use of pitressin and large amounts of potassium arising from their marked constrictor action on the coronary vessels. It seems to me just as important to emphasize that calcium is a powerful coronary dilator and that in the form of calcium gluconate it might be judiciously tried clinically when coronary dilatation is needed.

ACUTE OSTEOMYELITIS WITH STAPHYLOCOCCEMIA

A CLINICAL REPORT ON THE USE OF ANTITOXIN IN ITS TREATMENT

LENOX DIAL BAKER, M.D.

DURHAM, N. C.

AND

ALFRED RIVES SHANDS JR., M.D.

WILMINGTON, DEL.

In 1936 Joyner and Smith¹ reported from Duke Hospital excellent results with the use of staphylococcus antitoxin in the treatment of thirteen² cases of osteomyelitis in which staphylococcemia was present. In their series there were eleven survivals and two deaths as compared with eight survivals and eight deaths in their control group of sixteen similar cases in which therapy was identical except for use of antitoxin.

Previously Dolman³ had reported the results of a series of thirty-two cases of acute staphylococcal osteomyelitis with septicemia which had been treated with staphylococcus antitoxin; in his series there was a mortality rate of 31 per cent. In his control series Dolman, like Joyner and Smith, reported a mortality rate of 50 per cent.

Recently Stookey and Scarpellino⁴ stated: "It is remarkable that a vast accumulation of experimental facts pertaining to the protective properties of staphylococcal antitoxin against toxin should produce little clinical interest." We feel that the cause of this lack of clinical interest in the use of staphylococcus antitoxin

can be explained partly by an inadequate understanding of the criteria of its use and partly by the conflicting results that have been reported by several authors. In reviewing the work of the latter group it is of interest to note that no uniform criteria were followed in the use of the antitoxin, and the other therapeutic measures

Fig. 1.—Hemogram of a patient with acute staphylococcal disease.

employed were not commensurate with those outlined by Dolman and later by Joyner and Smith.

In 1894 Van de Velde⁵ discovered that the staphylococcus produced a filtrable leukocyte-destroying toxin, a leukocidin. Neisser and Wechsberg⁶ and numerous other investigators verified Van de Velde's original studies. The observations of these workers have since been expanded by Wadsworth and Hoppe,⁷ Burnet,⁸ Parker,⁹ Pike¹⁰ and others. These investigators have demonstrated a variety of effects of the staphylococcus exotoxin, of which the four most important are (1) the destruction of leukocytes, (2) the hemolysis of red blood cells, (3) the coagulation of plasma and (4) the necrosis of tissue. It has not been established whether these effects are the results of numerous exotoxins or are the result of one exotoxin with a variety of actions. Numerous strains of staphylococci are capable of producing the various effects, and it has been shown by Pantan and Valentine,¹¹ Burky,¹² Dolman¹³ and many others that the antitoxin stimulated by one strain of staphylococcus is capable of neutralizing the toxins of any other strains. On this postulate is based the clinical use of the staphylococcus antitoxin. Robertson¹⁴

measured the staphylococcus antitoxin titers in the blood of 305 normal persons and used the titer method in determining the level of antitoxin in the patient's blood. Weaver¹⁵ studied the antitoxin content in well over 200 cases of osteomyelitis and found that in acute osteomyelitis with a favorable prognosis staphylococcus antitoxin appears in unbelievable amounts, whereas in the fatal cases no antitoxin is present.

Joyner and Smith found that the severity of the toxemia in experimental rabbits could be estimated by the shift in the ratio of the mature to the immature polymorphonuclear leukocytes found in the circulating blood rather than by changes in the total white cell count. They found the same to be true in certain patients with acute staphylococcal disease (fig. 1). This decrease in the percentage of mature polymorphonuclear leukocytes was present in the thirteen children with acute osteomyelitis reported by them. In the eleven children of their series who survived, the administration of staphylococcus antitoxin¹⁶ was followed by general improvement, a decrease in the percentage of immature polymorphonuclear cells and an increase in the percentage of mature segmented cells (figs. 1 and 2), whereas in the two children that died the relationship of the mature to the immature cells failed to change following the administration of antitoxin. Stookey and Scarpellino called attention to the hopelessness of cases in which large bacterial emboli lodge in the cortex of the brain or in vital centers inaccessible to surgical drainage. One of their patients who failed to respond to antitoxin therapy died three days after onset of the illness. At necropsy only three small lung abscesses were found, but the viscera were very dark. They interpreted these phenomena as suggesting fixation of the toxin to the tissues. We feel that the latter hypothesis

Fig. 2.—Hemogram of a patient with acute osteomyelitis.

is worthy of further investigation and might well explain the fact that some patients fail to show any response to antitoxin even when apparently adequate drainage has been provided.

As Robertson has pointed out, "Its power to cause serious change in the vascular system is the factor that

makes staphylococcal osteomyelitis one of the most dreaded diseases occurring in the young." He is of the opinion that the severity of the disease depends not so much on the number of organisms present as on the individual's natural ability to destroy the organism by phagocytosis and to produce antitoxin to neutralize or render inert the toxins produced by the organism. He reported unsatisfactory results in nine cases of staphylococcal osteomyelitis in which intravenous antitoxin was

used. He did not give any review of what criteria he followed in selecting his cases and in administering the serum and he did not give the dosage used except in one case; it is therefore difficult to evaluate his data. There is one important factor which may have influenced his results, that is, his effort to combat the septicemia and toxemia without carrying out early drainage of the site of infection. We are convinced that early drainage is absolutely necessary if one is to combat the constant liberation of toxin from the focus. We have concluded

from our autopsy results that a lack of response to antitoxin therapy can in a large percentage of cases be attributed to incomplete drainage of the osteomyelitis or to the presence of inaccessible foci. Robertson's work was not primarily concerned with staphylococcus antitoxin and its use but dealt in detail with staphylococcus titers and toxoids; it is an excellent treatise on this subject and it should stimulate interest in the use of staphylococcus toxoid. Williams¹⁷ has reported the results of the use of staphylococcus antitoxin in the treatment of twenty-four cases of acute osteomyelitis and has compared the clinical course of this series with that of forty-two cases of acute osteomyelitis in which the antitoxin was not used. The size of his doses according to our methods was in the majority of instances entirely inadequate. His cases were evidently picked with no regard to the presence or absence of toxemia. He stated: "Blood cultures, performed in four instances, showed a staphylococcemia" and he concluded that the serum had not been of "much extra benefit"; however, he admitted that little comparison could be made between the potency of his serum and of that used by Dolman. His paper is a comprehensive review of acute osteomyelitis, but it confuses the purpose for which staphylococcus antitoxin should be used. It is not amiss at this time to state that staphylococcus antitoxin has one and only one role: the neutralization of the staphylococcus toxin or toxins which, when liberated in the circulating blood, cause the destruction of leukocytes, the hemolysis of red blood cells, the coagulation of plasma and the necrosis of tissue.

17. Williams, S. W.: The Early Treatment of Acute Staphylococcal Osteomyelitis, M. J. Australia 2: 459 (Sept.) 1937.

STATISTICS

Of 648 cases of staphylococcal disease reviewed in the preparation of this paper there were 103 cases with a definite staphylococcal septicemia; of these 103, in sixty-five there was osteomyelitis. This report is concerned primarily with the cases of osteomyelitis, but the statistics of the 103 cases of staphylococcal septicemia may be of general interest and are therefore recorded (table 1). Of the 103 patients sixty-one died and forty-two survived, a mortality rate over all of 59 per cent. Of the patients not treated with staphylococcus antitoxin forty-three died and thirteen survived, a mortality rate of 76 per cent; whereas of the forty-seven patients treated with staphylococcus antitoxin eighteen died and twenty-nine survived, a mortality rate of 38 per cent. The patients ranged in age from 3 weeks to 66 years; the average age was 20 years. The sixty-five patients with osteomyelitis ranged in age from 3 weeks to 62 years, with an average age of 15 years.

Table 2 shows the age groups of the patients with osteomyelitis and the results for each group. Sixty-five patients with osteomyelitis had proved staphylococcemia. Of these sixty-five there were thirty who did not receive staphylococcus antitoxin; of this group nine survived and twenty-one died, a mortality rate of 70 per cent. There were thirty-five patients treated with

antitoxin; of this group twenty-six survived and nine died, a mortality rate of 25.7 per cent. In the group treated with antitoxin the average duration of illness on admission was 7.6 days. In the group not receiving antitoxin the average duration of illness on admission was 9.8 days.

The blood picture expressed in colonies of staphylococcus per cubic centimeter of blood is shown in table 3. Of the group not receiving antitoxin there were only two survivors whose blood showed over one colony

per cubic centimeter and no survivors whose blood showed over ten colonies per cubic centimeter, whereas in the group receiving antitoxin there were eighteen survivors in whose blood there was over one colony per cubic centimeter, and eight of these eighteen showed over ten colonies per cubic centimeter. Of the nine fatal cases in which antitoxin was used, death was attributed to inadequate drainage in five cases, inaccessible foci in two and pneumonia in two. In three of these cases antitoxin therapy was not indicated as each showed a high ratio of mature leukocytes, and in two

of the fatal cases there was a favorable response to the antitoxin, that is, there was a shift of the hemogram to the mature side. We feel that in the latter five cases death was due not to the toxic effect of the staphylococcus but to the absorption of nonspecific toxins or to the infection of vital centers.

ROUTINE TREATMENT

As far as possible our routine treatment in suspected cases of osteomyelitis has been carried out according to the following plan but not necessarily in the order named (since the studies are made by several workers, and conditions of course vary in every case): An adequate history is obtained, and a complete physical examination is done. Sedation is carried out as indicated, and the dehydration which is usually present is combated by intravenous fluids in the form of physiologic solution of sodium chloride with 5 to 10 per cent dextrose. A hemoglobin determination is made and red blood cell and white blood cell counts are done. The leukocytes are differentiated to estimate the relative percentage of mature and immature polymorphonuclear cells, and it is on this relationship, regardless of what the total white cell count may be, that we determine whether or not the administration of antitoxin is indicated: antitoxin therapy is instituted if there is an increase in the percentage of nonsegmented and a rela-

Total.....	18	12

tive decrease in the percentage of segmented polymorphonuclear cells found in the circulating blood. Blood cultures are planted and the patient is grouped and matched for transfusions; preoperative blood transfusion of from 150 to 200 cc. is given; as a rule, the donor is bled of from 500 to 600 cc. and the remainder of the blood is given in twelve to twenty-four hours or postoperatively. If a diagnosis of osteomyelitis is made, the patient is prepared for immediate operation. The type and extent of operation depend on the individual features of the disease in each case and will be discussed later. It should be said here that immediate and adequate drainage is a prime requisite if the use of staphylococcus antitoxin is to be effective. Preoperative roentgenograms are made as a matter of record but have been of little if any diagnostic value in the earlier cases. Postoperative care will be outlined under the several headings that are to follow. As already stated, we use the hemogram picturing the relative percentage of mature and immature polymorphonuclear cells as the main guide in determining the degree of toxemia which may be neutralized by antitoxin therapy. The general toxemia of the patient, evidenced by high temperature, increased pulse rate, respiratory distress, flushed face, dilated pupils and sometimes delirium, is considered in outlining the general care but not as an indication for the use of staphylococcus antitoxin; the patient might well be neutralizing the staphylococcus toxin with his own antitoxin and his apparent toxic condition be due to other elements. Burnet has pointed out that other factors besides the production of toxin play a part in determining the fatal outcome in staphylococcal infection in animals. Stookey and Scarpellino

reported a case in which in their opinion death was caused by the absorption of necrotic products and the nonspecific toxins of necrotic tissue in a surgically accessible area that had not been adequately drained.

METHODS OF ADMINISTERING THE SERUM¹⁵

A skin test for sensitivity should be made intradermally with 0.1 cc. of the undiluted antitoxin; also 0.1 cc. of a 1:10 dilution of normal horse serum should be administered intradermally as a control. Frequently the patient responds negatively to normal horse serum and with an immediate urticarial wheal to the antitoxin. This variation indicates an antigen-antibody reaction in the skin and not a sensitivity to horse serum. Patients showing a reaction to the antitoxin should always receive the first dose intramuscularly, followed four hours later by intravenous antitoxin. As a general rule the first dose of the serum for children under 10 years of age has been 20,000 units administered intramuscularly. Children over 10 have received initial doses up to 40,000 units. If there is no reaction to the first dose, we advocate intravenous administration for the subsequent doses. The antitoxin is administered intravenously with a gravity apparatus. The amount of serum is estimated and twice its volume of saline solution is poured into the gravity apparatus. After the needle is in place, the antitoxin is poured on to the saline solution and administered slowly over a period of twenty minutes or longer. The initial dose is usually followed in four hours by an intravenous dose of from 40,000 to 60,000 units, depending on the size of the patient. The dose of from 40,000 to 60,000 units is repeated after twenty-four hours. Often this is sufficient to shift the white blood cells back to a favorable ratio. If this shift has not occurred in twenty-four hours, from 40,000 to 60,000 units is given intravenously every twenty-four hours until there is a favorable shift.

With the use of the new highly purified serum¹⁶ in the past three years we have had no case of serum sickness. One of our patients, aged 6 years, received 700,000 units and another patient, aged 8 years, received 600,000 units, each within a period of three weeks, and neither developed any sensitivity to the serum.

OPERATION

A detailed discussion of the relative virtues of early or delayed operation in the treatment of osteomyelitis is outside the scope of this paper; however, experience controlled by the results of eighteen necropsies (table 4) has taught us that if antitoxin therapy is to be effective it is necessary that all foci of infection receive early and adequate drainage in order that the constant absorption of the toxins may be eliminated. Our operative procedures vary according to the features of each case: when possible, we follow a modification of the treatment advocated by Orr,²⁰ that is, free drainage and absolute immobilization. At operation an opening of sufficient size and extent to drain the focus is made. Early in our series we frequently used multiple drill holes as outlined by Starr²¹ and have found this procedure satisfactory, but of late we have windowed the bone to assure adequate drainage; we are of the opinion that the results of the latter method are the more

15. The antitoxin used in this series of cases was administered with the direction of Drs. D. T. Smith and W. R. Haas. A more detailed study with the results of antitoxin in the treatment of experimental staphylococcal septicemia will be reported later by these authors.

satisfactory. It is rare that we find simple incision of a subperiosteal abscess sufficient to provide adequate drainage. In the cases in which this method of treatment was used the acute course has been prolonged and the extent of bony involvement increased. In carrying out the Orr method we deviate somewhat from his original recommendations: we irrigate the incision thoroughly with physiologic solution of sodium chloride but do not apply antiseptics as we feel it is futile to try to kill the infection locally and believe the damage done to the tissues by the antiseptics is detrimental to healing. In making our incision through the periosteum we do not reflect the periosteum but, as suggested by Albee and Patterson,²² incise round the area to be removed. Before windowing the bone we usually make exploratory drill holes into the suspected area to determine the presence of pus and its exact location. In order better to visualize the type of material coming from the openings, all drill holes are made with the incision filled with ether. After the exact site of infection is determined, the area is windowed or saucerized, depending on the acuteness of the illness. The defect is packed with petrolatum gauze to which an excess of petrolatum has been applied. We use 2 inch gauze with salvaged (finished) edges; we have found this type of material much better than that with the unsalvaged edges, as it does not ravel and leave loose threads embedded in the newly formed granulation tissue. The entire wound is filled with the petrolatum gauze and covered by a dry dressing. A plaster cast is then applied to immobilize the part in the optimal position for function. The dressing is not disturbed unless there is a rise in temperature or other signs of increased sepsis. The merits of this type of treatment have been well described by previous writers and need no further discussion here. Convalescent care consists of continued rest and immobilization until healing has taken place or at least until all danger of contracture and deformity has passed. A high vitamin, high caloric diet is augmented by cod liver oil, thiamin chloride and ascorbic acid.

Although our experience in its use is limited, we are of the opinion that staphylococcus toxoid is of definite benefit during the recovery period. Robertson has outlined in detail one method of administering the toxoid. Since the beginning of the preparation of our report Whitby²³ has found sulfapyridine to be an active chemotherapeutic agent in the treatment of staphylococcal infection in mice, and his work has been confirmed by Bliss and her associates.²⁴ Long²⁵ noted that the institution of sulfapyridine therapy was followed by a rapid sterilization of the blood in three of five patients ill with staphylococcal bacteremia. He did not report the degree of toxemia or the colony count per cubic centimeter in the blood of the patients treated. He was of the opinion that on the basis of the available experimental and clinical evidence careful therapeutic trials of the drug were warranted. McColl²⁶ has found sulfapyridine effective in the treatment of staphylococcal infection on the surfaces of the upper respiratory system but has not found the same to be true in undrained areas. Smith²⁷ has used sulfapyridine in a

number of cases treated with antitoxin and, although it is too early to give a final opinion, he states that it appears that the use of this drug in combination with antitoxin may be definitely superior to either treatment when used alone.

CONCLUSIONS

1. Staphylococcus toxins can be neutralized in vivo by commercial serum.
2. Antitoxin therapy is indicated only when the patient has failed to create sufficient autogenous antitoxin to neutralize the toxins present.
3. The degree of toxemia can be estimated for clinical guidance by the ratio of the mature to the immature polymorphonuclear leukocytes found in the circulating blood.
4. It is necessary to have early and adequate drainage of all foci of infection if antitoxin therapy is to be effective in combating the toxemia.
5. The antitoxin serum which we have used can be administered intravenously with safety and without the subsequent development of serum sickness.
6. The surgical and postoperative procedures as advocated by Orr in the treatment of acute osteomyelitis have been found to be the most satisfactory as well as the most practical form of surgical therapy.

ABSTRACT OF DISCUSSION

DR. JAMES B. WEAVER, Kansas City, Mo.: For over four years I have measured antitoxin in the blood stream and done Schilling counts, as Drs. Baker and Shands have done, in more than 200 cases of acute, chronic and recurrent osteomyelitis. I get more information from measuring the antitoxin content of the blood stream than I do from the Schilling count. The Schilling count is a much simpler test and is better from that standpoint; however, more things have to happen within the host to produce results and that gives more opportunities for greater error. I have found that in counting 100 cells, which I usually do, there is some variation. To get a really accurate Schilling count one should count several hundred cells. Most of the authors' patients as well as my own in the acute stage received numerous transfusions, and I wonder what the effect of the donor blood had on the Schilling count. The measurement of antitoxin in the blood stream is not foolproof. Theoretically it is not what one would have it, because there are other substances in staphylococcus toxin besides the hemolytic factor, which is the basis of this test. There are leukocythemia and the necrotic element, and this test is based on only one of these. To date it is not known whether these substances run parallel in toxin or not, but by measuring the antitoxin content daily I think I can prognosticate fairly well what is going to happen to the patient. It has been my experience that patients who do not make their own antitoxin do not survive. Those who do make their own antitoxin in a fair amount usually survive but as a rule run into difficulty later on. Their sinuses are much more chronic in healing, and they have much more recurrent osteomyelitis. In cases in which a tremendous amount of antitoxin is produced the prognosis for fairly prompt healing and against recurrence is quite good. As to the mortality in treating these patients with staphylococcus antitoxin, my series is in no way comparable to the authors'. I have never had a patient die of acute osteomyelitis with septicemia to whom I did not give antitoxin. The reason for that was that I was fairly certain that the patient was going to survive and I did not give the antitoxin. Patients who I thought would not survive received antitoxin. So I have a high mortality rate. I have seen positive hemograms, that is, favorable hemograms, as Drs. Baker and Shands show, mounting daily as the antitoxin tide has dropped, so those two factors are not parallel. They are in the first two weeks, but after that not at all.

DR. BEN L. SCHOOLFIELD, Dallas, Texas: I have for some years used an autogenous vaccine in a considerable number of cases of acute and chronic osteomyelitis. That apparently has been of considerable benefit, but when one is doing a great deal of surgery along with it one never knows which does the most

good. Certainly, the vaccines alone cannot be depended on. I tried that on one patient who refused surgery and apparently no particular benefit was obtained, but I do believe that the administration of an autogenous vaccine, made from the patient's own pus, is distinctly beneficial.

DR. LENOX D. BAKER, Durham, N. C.: As to the use of the titer method and the use of white cell counts, at our place the titer method as a clinical procedure is not practical at this time. We find that the white cell count can be followed by clinical clerks and that it is the most practical way we have of judging the amount of toxemia present. As to the value of blood transfusion without the use of antitoxin, all I can say is that our patients who were not given the antitoxin had just as many blood transfusions as the patients who were given the antitoxins. As to the amount of antibodies the donors might carry, we observed a boy aged 16 with osteomyelitis of the femur who had been given sixteen transfusions over a period of thirty-eight days. For the seventeenth transfusion we used an immunized donor; that is, a donor who had been immunized to the patient's own organism. Twenty-four hours after this donor was used the patient's white cell count shifted back to a normal ratio, his temperature dropped to normal and he made an uneventful recovery. I have no doubt that the donor's blood had a great deal to do with it, but we cannot always find such a donor and we do not know which donor will manufacture antitoxin. As to the use of autogenous vaccines, these cases are emergencies that are in need of immediate assistance if recovery is to be hoped for. At this stage vaccines and toxoids have not been of benefit in our hands.

MALE SEX HORMONE

CLINICAL APPLICATION

W. O. THOMPSON, M.D.

AND

N. J. HECKEL, M.D.

CHICAGO

The numerous claims and conflicting reports concerning treatment with male sex hormone make it desirable to define its use more precisely.

The testis consists essentially of two parts: (1) the seminiferous tubules, the most important function of which is to produce spermatozoa, and (2) the interstitial cells of Leydig, the most important function of which is to produce male sex hormone.¹ What relationship, if any, exists between these two structures is unknown. On the production of the male sex hormone depends the development of secondary sex characteristics, namely the growth of the penis, scrotum, prostate, seminal vesicles, epididymis, vas deferens, body hair, beard, pitch of the voice and, to some extent, skeletal growth, including the contour of the body. Observations of the last few years have demonstrated conclusively that a delicate balance exists between the anterior lobe of the pituitary and the testis.² The pituitary apparently stimulates the activity of the testis, which in turn may serve as a check on the pituitary itself. Various factors involved in the initiation of the pituitary stimulus are not clearly understood. There is some evidence that there may be two gonadotropic factors corresponding to two gonadotropic effects of the anterior lobe of the pituitary. One causes development of the follicles of the ovary and influences the function

of the seminiferous tubules in the testis (the so-called follicle stimulating hormone), and the other causes luteinization of follicles in the ovary and influences the activity of the interstitial cells in the testis (the so-called luteinizing hormone). Menopausal and castrate urines contain primarily the follicle stimulating material, while human pregnancy urine contains largely the luteinizing factor and is available under various trade names (follutein, korotron, A. P. L., antuitrin-S). The gonadotropic material from the serum of the pregnant mare (e.g. gonadogen, gamone) and commercial preparations prepared from the pituitary itself contain both factors. It is obvious that the testis may be stimulated selectively.

Two types of hormone therapy are now possible in hypofunction of the testis: (1) stimulation therapy with gonadotropic material and (2) substitution therapy with male sex hormone. With gonadotropic material the testis is stimulated to increased activity so that the testis itself produces more male sex hormone, and it is to be preferred in most instances in which the testis is capable of responding to stimulation. Examples of conditions in which stimulation is indicated are the Fröhlich syndrome, hypopituitarism with secondary hypogenitalism, and undescended testes. In substitution therapy the male sex hormone, which the testis itself is not capable of producing in sufficient quantity when stimulated, is supplied artificially. Examples of conditions in which it is indicated are eunuchism, eunuchoidism and all cases in which the testis is incapable of response because of atrophy or destruction (e.g. the orchitis of mumps). The male sex hormone has also been reported to produce improvement in patients with benign prostatic hypertrophy and to rejuvenate old men. It appears to alter the function of the normal testis as judged by decrease in spermatogenesis during its administration.

In just what form the male sex hormone is secreted by the testis is unknown. The most active substance isolated so far is testosterone, which is six times as potent as androsterone, the first androgenic material isolated from urine. Certain esters of testosterone are much more potent than testosterone itself and in clinical work the propionic acid ester (testosterone propionate³) is now most commonly used. In addition to testosterone, which has been isolated from the testis, and androsterone and dehydro-androsterone, which have been isolated from urine, twenty-seven related substances with male hormone characteristics have been prepared synthetically by the degradation of sterols, but these are not used therapeutically. For therapeutic purposes testosterone is made synthetically. It is of the greatest interest that from the ovary, testis and adrenal, which come from about the same location in the embryo, important substances have been isolated which show only slight differences in their chemical structure and which may all be derived biologically from cholesterol (estradiol, progesterone, testosterone, desoxycorticosterone).

Very little androgenic material has been recovered from the urine of young boys and girls from 6 to 10 years of age—only from 0.7 to 2 international units per liter. A marked increase in the amount found in urine begins at about the time of puberty, the urine of an adult male containing from 40 to 100 international units in twenty-four hours.⁴ The amount secreted appears

Read before the Section on Pharmacology and Therapeutics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

1. There is some evidence that the cells of Sertoli may produce a hormone different from that produced by the interstitial cells.

2. Various factors involved in the interrelation of the pituitary and testes have recently been reviewed by C. R. Moore (Gonadotropic Substances and Male Hormone Effects in the Organism, *J. Urol.*, to be published).

3. The testosterone propionate (oreton) used in this study was supplied by the Seehring Corporation.

4. Koch, F. C.: The Male Sex Hormones, *Physiol. Rev.* 17:151 (April) 1937.

to diminish with advancing years, but no accurate data are available. What role, if any, sex hormones play in embryonic development has not been established, but they may be responsible for the development of secondary sex characteristics. The well marked growth of the interstitial cell mass in the testis of the embryo would suggest this possibility.

For some reason not clearly understood, estrogenic material is found in male urine (the equivalent of 10 micrograms of theelin a day) and female urine is just about as rich a source of male hormone as male urine and contains from 30 to 100 international units in twenty-four hours.⁴ Koch has pointed out that human urine is unique in its androgenic content, the urine of the stallion, bull, ram and rat containing but little.

EUNUCHISM AND EUNUCHOIDISM

The value of male sex hormone is shown best by its effect on individuals with complete absence of testicular function, namely castrates and eunuchoid individuals. The persistence of bilateral intra-abdominal cryptorchidism beyond the age of puberty commonly results in a condition similar to that produced by castration early in life. However, eunuchoidism is by no means an inevitable result of bilateral failure of testicular descent. In adults with bilateral intra-abdominal cryptorchidism the interstitial cells may show a surprising degree of function, as judged by the development of a normal size penis and prostate and a considerable amount of pubic hair. When the penis of such a person develops normally the body contour is usually normal, but when genital growth fails to take place a state of eunuchoidism usually results. Eunuchoid individuals are usually tall and often slender with the extremities long in proportion to the trunk. The shoulders and chest are narrow. The voice is high pitched and the person is very shy, effeminate and high strung. There may be a feeble attempt at the production of pubic hair but there is usually little or no axillary hair, no beard and no hair on the chest, abdomen, arms or legs. The genitalia remain infantile. The prostate is usually not palpable. The muscles are small and feminine in type. In striking contrast to patients of the Fröhlich type, they often weigh less than normal and often show no development of breast tissue. Eunuchoidism appears to illustrate the effect of testicular deficiency per se, in contrast to the secondary hypogonadism of the Fröhlich syndrome.

In the treatment of eunuchoidism it is necessary to use large doses of testosterone propionate (from 50 to 100 mg. daily). The doses originally recommended (from 1 to 5 mg. daily) are totally inadequate. During the administration of large doses of this material to eunuchoid individuals the following effects are noted:

1. The gradual appearance of the secondary sex characteristics of the adult male. The infantile penis may become normal in size, the prostate develops, and hair grows in the pubic and axillary regions, on the face and on other parts of the body. The pitch of the voice rapidly assumes its characteristic masculine quality. Erections and seminal emissions become very frequent. Priapism has been described.

2. A marked increase in appetite and body weight (as much as 40 pounds [18 Kg.] in four months). The patients do not become obese but show an enormous increase in the size, firmness and strength of muscles. The material appears to stimulate development of the muscular characteristics of the normal male, whereas

in the eunuchoid state the muscle development resembles that of the female. This change is very dramatic.

3. An increase in basal metabolism of as much as 30 points. In our patients who received large doses, the rate was raised above normal.

4. An increase in vigor and sense of well being. The patients are capable of and have the initiative to do much more work, both mental and physical. They seek and become much more proficient in games involving muscle coordination and physical stamina.

5. Loss of their effeminate characteristics. Whereas before treatment they tend to run away from arguments and physical combat, after treatment they tend to welcome opportunities to demonstrate their physical prowess.

A typical example of what may be accomplished with this material is shown in the illustrations.⁵ As in all conditions involving stimulation, the response is determined not only by the stimulating substance but also by the susceptibility of the organ stimulated. There are thus variations in the amount of growth of the penis that may be produced with large doses. From our observations it would appear that the rate at which the development of secondary sex characteristics can be induced cannot be accelerated beyond a certain point. It is to be remembered that the changes associated with normal puberty occur gradually over a period of several years. The details of treatment in eunuchoid individuals are still to be worked out. It is probably necessary to continue intensive therapy for between one and two years and then continue with maintenance therapy for the rest of the patient's life. What the dose for maintenance will prove to be is unknown. In order to simulate natural phenomena and to prevent

Fig. 1.—Appearance of E. W., a eunuchoid patient aged 18, Nov. 11, 1937, before treatment was started. Height 67 inches (170 cm.), weight 111½ pounds (50.5 Kg.).

the development of the skeletal characteristics of the eunuchoid state, it is probably desirable in cases of bilateral intra-abdominal cryptorchidism to begin treatment just before the age of normal puberty, namely, at about the age of 11 years.

5. Genital growth in eunuchoid persons has been reported by the following:

- Hamilton, J. B.: Treatment of Sexual Underdevelopment with Synthetic Male Hormone Substance, *Endocrinology* 21: 649 (Sept.) 1937.
Kenyon, A. T.; Sandiford, Irene; Bryan, A. H.; Knowlton, Kathryn, and Koch, F. C.: The Effect of Testosterone Propionate on Nitrogen, Electrolyte, Water and Energy Metabolism in Eunuchoidism, *Endocrinology* 22: 135 (Aug.) 1938.
Rubinstein, H. S.: The Induction of Sexual Maturity in the Genitally Hypoplastic Adult Through the Use of Testosterone Propionate, *J. A. M. A.* 111: 1818 (Nov. 12) 1938.
McCullagh, E. P.: Treatment of Testicular Deficiency with Testosterone Propionate, *J. A. M. A.* 112: 1037 (March 18) 1939.

In a previous communication to *THE JOURNAL* we⁶ discussed in detail various aspects of the treatment of undescended testis with the anterior pituitary-like principle of pregnancy urine. This material works in cryptorchidism by stimulating the interstitial cells of the testis to produce male sex hormone and produces descent in about one fourth of the cases in young boys. The same results can be produced with male sex hormone itself, but since it may injure the testis it does not appear to be as suitable as stimulation therapy. In rare instances it may cause descent of the testes in eunuchoid individuals. It should be pointed out that both anterior pituitary-like substance and male sex hormone may cause excessive genital growth in young boys and that both may stimulate the rate of skeletal growth. Whether or not this is followed by retardation of growth, so that the final height of the body is reduced, as is the case of some interstitial cell tumors of the testis, is unknown. Both substances are to be used with caution in young boys.

Fig. 2.—Appearance of the patient Dec. 13, 1938, after 629,500 rat units of anterior pituitary-like substance had been given over a period of thirteen months. Height 68½ inches (174 cm.), weight 112½ pounds (51 Kg.).

FRÖHLICH SYNDROME

In cases of the Fröhlich type the effect of stimulation therapy should be tried before male sex hormone is used. Large doses of gonadotropic factor of pregnancy urine are very effective in this condition. If the testes do not respond to stimulation, large doses of testosterone propionate may be used.

BENIGN PROSTATIC HYPERTROPHY

In contrast to the numerous reports of beneficial results from the use of male sex hormone in benign prostatic hypertrophy, our experience with this material in such cases has been disappointing. Since the male sex hormone causes development of the prostate in the first place, it is not easy to understand how its use in benign prostatic hypertrophy would be beneficial. In twenty-two cases of this disorder, testosterone propionate in daily intramuscular injections produced little improvement in the symptoms and clinical course. No noteworthy reduction in the residual urine occurred.

The twenty-two patients fell into two groups. In group 1, made up of nine patients, the average age was 72 years, the youngest patient being 67 and the oldest 91. The prostate gland was enlarged in three

cases to grade 3 plus, in four to grade 2 plus and in two to grade 1 plus. Three patients had an average residual urine of from 200 to 500 cc., two of from 100 to 200 cc. and four of less than 100 cc. They were treated from seven to fifty-six weeks, receiving the testosterone propionate in total amounts of from 560 mg. to 3,200 mg. Two patients showed a slight reduction in frequency during the day and two patients experienced temporarily an increase in libido and the frequency of erections, but no noteworthy decrease in residual urine occurred in any of the nine cases. In two cases in this group an acute retention developed during the administration of the hormone. In group 2, made up of thirteen patients, the ages ranged from 58 to 82 years (average 70 years). The prostate was enlarged in one case to 4 plus, in three cases to 3 plus and in nine to 2 plus. In four cases the average residual urine varied from 100 to 200 cc. and in nine it was less than 75 cc. The patients were treated from four to fifty-two weeks, the total amount of testosterone propionate varying from 200 to 3,990 mg. An analysis of the results in this group showed that two patients discontinued treatment because they felt that they were getting worse. In four cases a temporary improvement in erections was noticed; three patients showed a reduction in nocturia; one also noticed a reduction in frequency during the day. The residual urine of the four patients who had more than 75 cc. showed no noteworthy reduction. Conclusions based on smaller quantities than this are not reliable.

Some improvement has been reported from the use of female sex hormone in the treatment of benign prostatic hypertrophy, but these reports are yet to be confirmed with well controlled data.

STERILITY

Since treatment with male sex hormone represents primarily substitution therapy, it does not appear to be indicated in the treatment of male sterility. In fact, one of us⁷ has been able to depress the number of spermatozoa in men with normal counts almost to the

Fig. 3.—Appearance of the patient May 4, 1939, after 44 mg. of testosterone propionate had been given over a period of four and one-half months. Height 72 inches (183 cm.), weight 147½ pounds (66.9 Kg.). The very slight response to large doses of anterior pituitary-like substance stands in striking contrast to the response to testosterone propionate. Hair, which cannot be seen in the picture, developed all over the body. Note the increase in the size of the muscles. The prostate, not palpable before administration of testosterone, became 2 cm. in diameter and bulged into the rectum. There was a marked change in the quality of the voice. Neither testis was palpable before or after treatment.

6. Thompson, W. O., and Heckel, N. J.: Undescended Testes: Present Status of Glandular Treatment, *J. A. M. A.* 112: 397 (Feb. 4) 1939.

7. Heckel, N. J.: Production of Oligospermia in a Man by the Use of Testosterone Propionate, *Proc. Soc. Exper. Biol. & Med.* 40: 1 (April) 1939.

point of azoospermia by the use of testosterone propionate. The spermatozoon count returned to normal after the omission of treatment. In other words, in an individual with normal testicular function it would appear that testosterone propionate produces at least a temporary injury to the seminiferous tubules. These results appear to contraindicate the use of male sex hormone in most cases in which the testes are capable of producing spermatozoa. The problem of sterility is a complicated one and its treatment at present unsatisfactory. In some instances deficiencies in quantity and quality of spermatozoa appear to be related to deficiencies in the function of the anterior lobe of the pituitary. Some improvement in therapy may be expected from the development of a more potent gonadotropic factor from the pituitary. The role of the gonadotropic material from the serum of the pregnant mare in the treatment of sterility in the male is still to be determined. The value of the anterior pituitary-like factor is questionable in sterility because it stimulates primarily the interstitial cells.

THE MALE CLIMACTERIC

There is no definite period of loss of sexual function in the male like the menopause in the female. Nevertheless there does occur some waning of sexual activity with advancing years, the age varying tremendously from person to person. More than 50 per cent of men over 70 years of age are reported to show spermatozoa.⁸ Brown-Séquard and others have associated the fatigue and decreased vitality of advancing age with decrease in sexual vigor, and a condition has been described in some males resembling the female climacteric. It is probably true that some men of this type will be helped by male sex hormone,⁹ but the details of this form of therapy are still to be worked out.

IMPOTENCE

The promiscuous use of glandular therapy in impotence is to be deplored. Many cases are psychogenic in origin. The first thing is to determine the cause of the impotence. If it is related to a deficiency of testicular function, then improvement may be expected from glandular therapy which may be of the stimulation or substitution type, depending on the capacity of the testes to respond. One man aged 56 was cured of impotence by the administration of the anterior pituitary-like principle from pregnancy urine in a dose of 1,500 rat units three times a week. Until more is known about the possible harmful effects of this type of therapy in old men it is wise to proceed cautiously.

UNTOWARD RESULTS

Three of our eunuchoid patients (from 18 to 26 years of age) receiving large doses of testosterone propionate have shown transitory edema of the ankles, but during the period of edema they felt unusually well and were very anxious to continue with the treatment. One other eunuchoid patient complained that palpitation and tachycardia were so marked that he had to discontinue treatment for a while. Three old men with prostatic hypertrophy had edema of the ankles and shortness of breath during treatment. Thompson¹⁰ reports the development of generalized puffy edema, acne of the face and trunk and precordial pain. In one of his cases

precordial pain was so marked that treatment had to be discontinued. In younger men the edema may be caused by retention of sodium and other electrolytes, while in older men it may be caused by cardiac failure resulting from increased activity. The patients who are receiving this material must be followed for a long time to determine whether or not there are any untoward late complications.

SUMMARY

1. Testosterone propionate is an important therapeutic agent.
2. Its administration represents primarily substitution therapy, in contrast to stimulation therapy with gonadotropic material.
3. Its use is indicated in conditions in which the testis is incapable of responding to stimulation.
4. Its most important application is in the treatment of castrate and eunuchoid persons.
5. It may cause a marked reduction in the number of spermatozoa in normal men. For this reason it is

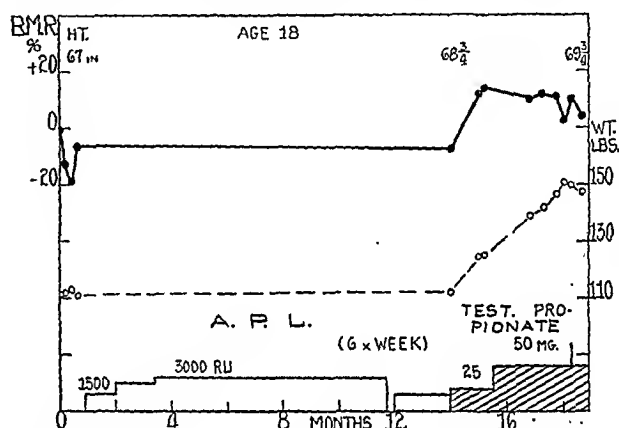

Fig. 4.—Changes in the basal metabolism and weight of the patient during treatment.

contraindicated when the testis is capable of normal function and it is probably of no value in the treatment of sterility.

6. Although it is as effective as the gonadotropic factor of pregnancy urine in undescended testes, treatment with the latter is to be preferred because of possible injury to the testis with male sex hormone.

7. It does not appear to be effective in the treatment of benign prostatic hypertrophy.

8. In the treatment of impotence it is indicated only in those cases in which the natural production of male sex hormone is deficient.

9. Its value in reviving the sexual, mental and physical vigor of old men is still to be determined.

ABSTRACT OF DISCUSSION

DR. ELMER L. SEYRINGHAUS, Madison, Wis.: I feel that there is a very definite clinical syndrome which is coming to be appreciated in larger numbers in the last decade or so under the term male climacteric. It has its drawbacks because there is not the same objective evidence of change which the female shows. However, the experience that I have had in a more limited group of cases than that of the authors' indicates that the testosterone is definitely effective in the relief of subjective complaints, more largely of the psychic complaints than of the autonomic and somatic complaints. The testosterone is being used at a time when there is no desire to stimulate or maintain testicular function, and at a time when prostatic hypertrophy

is common. Since testosterone is a material which is known to stimulate prostatic growth, it must be used with some caution until it becomes known whether it is a factor in stimulating the morbid hypertrophies or malignant diseases of the prostate. I wish it were possible for Drs. Thompson and Heckel to tell about the comparative results between the pregnant urine gonadotropic material which they have used so largely and the genuine pituitary gonadotropic materials. I have long felt that the genuine pituitary material would be preferable in those cases in which the objective is the improvement of fertility, the stimulation of the spermatogenic tissues, since spermatogenic tissues show so little or no response to the pregnancy urine material. I wonder if the authors have enough comparative data on the same patient treated with one preparation for an adequate period and then with the other to know whether one of these preparations, pregnancy urine or pituitary material, is superior, judging either by descent of the testes or by the development of the external genitalia. Another question is about the regression of the gains after therapy is stopped. How much of the gain in size of genitalia, how much of the gain in weight, how much of the gain in behavior remains after testosterone is no longer used? Does this require maintained therapy in the treatment of the eunuchoid? There is almost a corollary to that. What should be the objective in treating a eunuchoid? Is there any reason to develop a bigger penis or to develop more hair to increase the frequency with which a man has to shave? It would be my feeling that the only obvious reason to treat a eunuchoid, granting he is permanently infertile, would be if he is socially handicapped or psychologically handicapped and can be relieved from those stigmas sufficiently to become a more normal member of society.

PROF. ERNST LAQUEUR, Amsterdam, Netherlands: It is a great honor for me to speak in your Association and it is also a great pleasure to me to hear about testosterone, which my collaborators and I developed four years ago. We did not expect directly that this substance would have such great clinical value and that it would be so widely known. It is true that the large number of experimental and clinical trials became possible only after the synthetic preparation of testosterone by the procedures of Ruzicka and Butenandt. There are two questions I want to discuss with Dr. Thompson: (1) testosterone and spermatogenesis and (2) testosterone and prostate hypertrophy. 1. It is important if experimental evidence supports the impression in the clinical application of testosterone that with suitable doses the spermatogenesis is improved. In hypophysectomized rats spermatogenesis ceases unless the rat is treated with testosterone propionate, which prevents the loss of spermatogenesis. Clinical cases are reported in the literature and I have had personal experience with two cases in which moderate doses of testosterone restored spermatogenesis and cured sterility. One case of course gives no absolute evidence, but still it shows that spermatogenesis is not interfered with. 2. The treatment of mice with estrogenic substances induces an enlargement of the prostate and ducts of the seminal vesicles and ductus deferens. There are important structural changes (metaplasia of the epithelium, cornification and the like), which remind one of estrous changes in the vagina; de Jongh spoke about "estrus in the prostate." When with the similar treatment the administration of male hormone is combined, the pathologic changes of the prostate are prevented. This is experimental evidence in favor of the effect of male hormones on the prostate. Prostate hypertrophy can also be produced in young dogs by treatment with estrogenic substances. When this treatment is combined with injections of gonadotropic substances, which stimulate the animal's own testis to produce male hormone, hypertrophy of the prostate can be prevented and the naturally occurring hypertrophy in old dogs can so be cured. In 500 human cases I am informed that in more than two thirds some result has been obtained by male hormone. Such statistics may perhaps be considered as evidence in favor of a treatment such as that of hypertrophy of the prostate with male hormone. The lack of positive results in the authors' patients may be due to the fact that these were late cases, treated as outpatients, while clinical treatment was needed.

DR. WILLARD O. THOMPSON, Chicago: As pointed out in the paper, there probably is a condition in certain aging men in which the use of testosterone may be beneficial, not so much

because it affects their sexual function as because it increases their mental and physical vigor. But I do think that it is important to proceed cautiously, because the tendency is, once a potent material becomes available, to use it in many conditions in which it is not indicated. Dr. Sevringhaus asked if we had any evidence to suggest whether or not gonadotropic material prepared from the anterior pituitary might be preferable to that from the urine of pregnant women. Theoretically, the pituitary material should be preferable because in patients with hypogonadism one is interested not only in increasing the production of androgenic factor but also in influencing the function of the seminiferous tubules. However, there is no gonadotropic preparation of the anterior pituitary at the present time that is potent enough for routine clinical use, and that was why I said I thought that the pregnancy urine material was to be preferred at present, even though it is far from ideal. Dr. Sevringhaus also asked whether the increase in genital growth showed regression when treatment was omitted. Some regression in the size of the genitalia usually occurs after omission of the anterior pituitary-like principle, the extent varying greatly from patient to patient. In persons of the eunuchoid type, the effect of treatment with androgen is dependent on constant stimulation. While I do not know in detail the effects of omission of treatment, it is probably true that these patients will require some treatment throughout life, because the administration of androgenic substance merely represents substitution therapy. The most important aspect of treatment of the eunuchoid state with androgen is its stimulation of mental and physical vigor and production of a normal psychologic and emotional status. The emotional and psychologic changes in eunuchoid persons are very striking. Dr. Laqueur referred to his very interesting work with androgen which we all know about. He spoke about its being better to use small doses. I must say that we had to use very large doses of this material to produce genital growth in eunuchoid persons. As to the effect of this material on patients with benign prostatic hypertrophy, all I can do is to repeat our results, namely, that we have been unable to obtain any objective evidence of beneficial effect.

MANAGEMENT OF BENIGN STRICTURE OF THE ESOPHAGUS

PORTER P. VINSON, M.D.

RICHMOND, VA.

The frequency with which benign (cicatricial) strictures of the esophagus require dilation has produced the impression among physicians that lesions of this type occur more often than other diseases which cause dysphagia. Contrary to this belief, benign stricture occurs less often than carcinoma and cardiospasm, and with approximately the same frequency as pharyngo-esophageal diverticulum. Although benign stricture from swallowing lye is probably encountered less frequently now than prior to legislation requiring that lye be labeled poison, the total number of proved cases of cicatricial stricture has remained practically constant for the past twenty years. Constancy in the incidence of benign stricture has resulted, no doubt, from more accurate recognition of inflammatory lesions in the esophagus in which the cause of inflammation is not known.

Any inflammatory process involving the wall of the esophagus may produce sufficient contraction when healing occurs to reduce the lumen of the esophagus and interfere with passage of food into the stomach. Since formerly one tenth and now one fifth of benign strictures result from idiopathic inflammatory processes and since progressive dysphagia is the only significant symp-

Read before the Section on Gastro-Enterology and Proctology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

tom in this group of cases, it is possible that many lesions which are now recognized as benign were previously considered malignant. Differentiation of benign from malignant stricture may not be possible, and all strictures in the esophagus should be treated as though they were benign unless malignant disease can be proved.

A frequent cause of benign stricture, which was recognized but rarely in the past, is prolonged intermittent ulceration and healing at the junction of the esophagus and stomach that occurs in cases of so-called congenital shortening of the esophagus with hernia of a portion of the stomach through the esophageal hiatus in the diaphragm. Many such cases have been reported as peptic ulcer of the esophagus with formation of stricture.

Stricture from a simple inflammatory process that involves the wall of the esophagus is single and usually located in the lower portion of the organ. When a caustic is swallowed, the lumen of the entire esophagus may become stenosed or there may be single or multiple areas of narrowing. Frequently one of the strictures is in the upper portion of the esophagus. Superficial areas of esophagitis rarely produce sufficient scarring to reduce the lumen of the esophagus and interfere with deglutition. When inflammation involves the muscular layers of the esophagus, contraction occurs and dysphagia follows.

Difficulty in swallowing depends as much on reduction of elasticity of the wall of the esophagus as on actual narrowing of the lumen of the tube. This fact explains the severity of dysphagia in carcinoma when the lumen through the esophagus is fairly large, but elasticity of the wall of the esophagus is greatly reduced, as contrasted with relatively easy deglutition in benign stricture when the lumen is small but the wall more elastic. Infiltration of the muscular layers of the esophagus in carcinoma reduces elasticity of the tube and causes difficulty in swallowing, whereas a patient who has a carcinomatous growth in the esophagus without involvement of the muscular coats may experience little or no difficulty with deglutition. Multiple areas of narrowing in the esophagus may not be associated with a greater degree of dysphagia than is observed in cases in which there is a single stricture.

In burns of the esophagus from ingestion of strong inorganic acid and solutions of lye or ammonia, the severity of the burn is usually dependent on the concentration and amount of solution that has been swallowed. Although this is not always true and severe extensive stricture may follow ingestion of a small amount of caustic, yet patients who have intentionally swallowed a large amount of a concentrated solution of acid or alkali usually have multiple areas of stenosis of the esophagus, if they survive.

One must remember that strictures may occur in the stomach when a large amount of caustic, acid or formaldehyde has been swallowed. Formaldehyde rarely, if ever, produces serious erosion of the esophagus but, when retained in the stomach, it may cause extensive ulceration. In order that strictures in the stomach and especially at the pylorus may not be overlooked, roentgenoscopic examination of the stomach should be made of all patients who have swallowed a large amount of a corrosive substance. In most cases roentgenoscopic study should be deferred until the lumen of the esophagus has been dilated sufficiently to permit free deglutition.

Sodium or potassium hydroxide in granular form is rarely introduced into the mouth except accidentally.

It is seldom swallowed, and burns from it are usually limited to the mouth and lips. Stricture of the mouth may occur following burns of the lips and may require plastic operation. Immediate treatment of an injury of this type consists of removal of as much of the caustic as possible with water and application of olive oil to the burned surface.

When a solution of lye has been swallowed, a large amount of olive oil should be given by mouth and supportive measures should be instituted. It is questionable whether attempts should be made to wash the stomach, because introduction of a stomach tube is associated with trauma. Daily introduction of rubber tubes of increasing size immediately following ingestion of a caustic has been advocated to prevent formation of stricture, but I have not had any experience with this type of treatment. When acid has been swallowed, administration of magnesium hydroxide as an antidote is preferable to sodium bicarbonate.

Regardless of the type of chemical that has been ingested, pain and swelling usually prevent deglutition for three or four days. During this period an adequate amount of fluid should be administered by various routes, especially intravenously. As soon as the immediate inflammatory reaction has subsided, fluid can be taken by mouth, and within a week the patient is usually able to swallow soft food.

As healing progresses, the lumen of the esophagus decreases in size, and within a month or six weeks contraction of scar tissue may become so pronounced that there is complete symptomatic obstruction. If the patient is permitted to reach this stage of dysphagia without having swallowed a thread, gastrostomy may be considered necessary. If, however, a size D twisted silk thread has been swallowed as soon as the initial reaction of the burn has subsided, dilation may be performed when necessary without subjecting the patient to the risk, discomfort and expense of gastrostomy.

When a patient has ingested even a small amount of acid or caustic, a thread should be swallowed and kept in the esophagus until treatment by dilation is required or until it has been determined that a stricture is not present. When the patient is a small child, it is advisable to introduce the thread through a nostril or to withdraw it through the nose after a yard or more has been swallowed, so that the child cannot sever or fray the thread with his teeth.

Even when a patient seems to have complete closure of the esophagus and gastrostomy appears necessary, effort should be made to introduce a thread through the esophagus while fluid is administered preparatory to operation. In most cases a thread will pass through the esophagus although obstruction may seem to be complete, and, as soon as a thread has entered the stomach, fluid can be swallowed. The thread seems to promote passage of fluid through the esophagus just as a urethral filiform bougie facilitates passage of urine through a urethral stricture.

Gastrostomy is associated with a mortality rate of at least 10 per cent and requires hospitalization for ten days or longer. It adds to a patient's discomfort and should seldom be required if a swallowed silk thread is utilized in treatment. Another disadvantage of gastrostomy which is rarely emphasized is that the esophagus may close completely after a tube is introduced into the stomach and the immediate emergency is mitigated. Closure can be averted by having the patient swallow a thread and allowing it to remain in the lumen of the stricture until dilation can be performed. How-

ever, even though this precaution is not observed, complete anatomic stenosis of the esophagus seldom occurs. Recently I observed a patient with cicatricial stricture of the esophagus following ingestion of hydrochloric acid, who had had complete symptomatic occlusion for eight years. Even after this length of time the patient was able to swallow a thread, and normal deglutition has been restored. Gradual dilation of benign stricture of the esophagus with metal sounds will eventually result in restoration of normal swallowing.

Almost all strictures can be dilated to size 30 French at the first treatment, and the size can be gradually increased to 45 French. Not more than one sound should be passed through the esophagus at each treatment, and the interval between dilations and the size of the dilators should be gradually increased. It is advisable to pass dilators from above downward, even when gastrostomy has been performed and the thread

has been withdrawn from the abdominal opening. Passage of large dilators from below upward is attended with greater discomfort and the abdominal wound is subjected to unnecessary trauma.

Esophagoscopy is not necessary in the management of the majority of cases in which there is a benign stricture of the esophagus. Direct inspection of the esophagus is desirable for patients with strictures which may be benign, when the etiology is uncertain, or in instances in which sudden complete obstruction may have resulted from impac-

Appearance of patient mentioned in text, for whom normal deglutition has been restored following complete symptomatic obstruction of esophagus for eight years.

tion of a foreign body within the lumen of the stricture. However, dilation of strictures through an esophagoscope is attended with greater discomfort and risk than when dilators are passed into the stomach over a guiding thread. If gastrostomy is contemplated and the patient has difficulty swallowing a thread, esophagoscopy should be performed to ascertain whether or not the opening through the stricture is sufficiently large to permit passage of a small ureteral catheter which may be used as a guide for introducing dilating sounds into the stomach.

I have not had any experience with the use of heated bougies as suggested by Dean. Cutting of strictures by various methods is associated with unnecessary risk and discomfort. Impermeable stricture of the esophagus is seldom encountered, but, when anatomic stenosis exists, attempts to restore the lumen of the esophagus almost always result fatally. It is my belief that, when the lumen of the esophagus has been obliterated, establishment of an opening through the scarred tissue is impossible. Reconstruction of the esophagus because

of benign stricture has been accomplished in a few cases, but the risk of operation is great and the functional result has not been entirely satisfactory.

SUMMARY

1. Benign stricture of the esophagus occurs less frequently than carcinoma or cardiospasm.

2. In 20 per cent of cases in which there is stricture of the esophagus the cause cannot be ascertained. In these cases carcinoma is usually suspected, and accurate diagnosis may not be possible even following esophagoscopy examination and removal of tissue for microscopic study. Unless carcinoma can be proved, stricture of the esophagus should be considered benign.

3. Congenital shortening of the esophagus with herniation of a portion of the stomach through the diaphragm is frequently associated with stricture at the junction of the esophagus and stomach.

4. When a thread is employed as a guide for passing sounds, a benign stricture can be dilated with a minimal amount of risk and discomfort and with an excellent functional result.

5. Complete anatomic stenosis of the esophagus rarely occurs and can always be prevented by having the patient swallow a thread and allowing it to remain within the lumen of the esophagus until dilation has been accomplished. A patient was able to swallow a thread after having obstruction of the esophagus for eight years. Normal deglutition was restored by gradual dilation of the areas of stenosis.

6. Gastrostomy is seldom necessary in the management of benign stricture of the esophagus and adds to the risk of treatment.

7. In order that stricture at the pylorus may not be overlooked, roentgenoscopic examination of the stomach should be made in patients who have swallowed a large amount of a corrosive substance. Roentgenoscopic study should be deferred, however, until after the lumen of the esophagus has been restored by the passage of sounds.

ABSTRACT OF DISCUSSION

DR. JOHN H. FITZGIBBON, Portland, Ore.: Important advances in medicine are usually based on simple principles, and I feel that the introduction of the silk thread as a guide in the treatment of stenosis of the esophagus was one of the truly great advances. Regardless of the type of dilator used, the silk thread guide has made the passage of instruments a comparatively safe procedure in experienced hands and has saved patients much unnecessary discomfort and risk. I generally use the metal olive type of dilator originated by the late Dr. B. W. Sippy, because I believe that the piano wire guide, passed over the original silk thread guide, renders the procedure somewhat more safe than the thread alone. However, any one doing this work must be prepared to vary his technique at times, owing to individual peculiarities of the case and sometimes to devise modifications of existing instruments or to originate instruments adapted to immediate needs. Dr. Vinson's reminder that benign stenosis of the esophagus is rarely infrequently caused by conditions other than the swallowing of corrosives deserves attention particularly since congenital shortening of the esophagus is still frequently misdiagnosed. Legislation requiring that preparations containing lye bear a "poison" label has surely reduced the incidence of lesions due to the accidental swallowing of such corrosives. However, such labels have at times led to the taking of lye preparations with suicidal intent. This spring I observed two patients who swallowed drano, an effervescent lye mixture used for clearing out drain pipes. The author has emphasized the fact that

gastrostomy is seldom necessary in cases of corrosion if a thread is swallowed early, and I wish to mention the desirability of early and adequate dilation, especially in children. I have had experience with a few children who were allowed to struggle along on liquids and an inadequate diet for several years, with resultant evidence of developmental deficiency, seen particularly in the teeth. I agree with Dr. Vinson that esophagoscopy is usually not necessary in the management of patients with benign stricture of the esophagus unless there is doubt as to diagnosis or possibility of impaction of a foreign body. Certainly, treatment with a dilating instrument passed over a thread or a piano wire guide is much less uncomfortable and continues to give splendid results with reasonable safety.

RESPIRATORY ALKALOSIS DURING ANESTHESIA

AN EXPERIMENTAL STUDY IN MAN

M. H. SEEVERS, Ph.D., M.D.

R. T. STORMONT, Ph.D.

H. R. HATHAWAY, M.D.

AND

R. M. WATERS, M.D.

MADISON, WIS.

Increased pulmonary ventilation in the human individual, whether voluntary or involuntary, is accompanied by a series of biochemical and physiologic changes which are proportional to the intensity and duration of hyperventilation. The resulting symptoms and signs are numerous,¹ but certain of these are reasonably characteristic. Dizziness, blurring of vision, and numbness and tingling of the extremities are frequent early symptoms. Excessive pulmonary ventilation, long continued, results usually in spasms of the muscles of the face, hands and feet. In some persons these signs are accompanied or followed by laryngeal stridor, opisthotonos, generalized convulsions and unconsciousness. Physical and nervous fatigue are common sequels to the episode and may persist for several days.

The exact biochemical basis for these changes in the irritability of nerve cells has not been clearly established. It is probable that some of the symptoms and signs are initiated by the train of events which follow local restrictions in blood flow secondary to the alkalosis. Schneider² and Collier, Densham and Wells,³ among others, have demonstrated a marked peripheral constriction, and it is not unreasonable to believe that a similar constriction may occur in cerebral vessels, since they are known to respond readily to chemical alterations in the blood.

It is apparent from the literature that the integrity of the cardiovascular system as a whole is maintained even during severe respiratory alkalosis. Norlin⁴ has

established that the cardiac output, the pulse rate and the consumption of oxygen increase in proportion to the intensity of hyperventilation. Although Henderson, Prince and Haggard⁵ observed a fall in venous pressure in short experiments, this has not been confirmed by Schneider,² who obtained an increase in both capillary and venous pressure. Arterial pressure changes are insignificant. A slight rise or a slight fall may accompany voluntary hyperpnea⁶ or those clinical states associated with hyperventilation.⁷ We have failed to find a description of cardiovascular changes associated with hyperventilation in man which might be rightfully termed shock, according to the modern definition or usage of this term.

Until recently these relatively minor and seemingly compensable effects of respiratory alkalosis on the cardiovascular system of man were difficult to harmonize with the more profound changes which are observed in the anesthetized animal when the latter is subjected to excessive pulmonary ventilation. Henderson⁸ was the first to describe experiments in which circulatory failure and "fatal apnea" resulted from hyperventilation of the anesthetized dog. These observations served as the basis for his well known theory of acapnial shock. Numerous investigators⁹ have observed the arterial hypotension which he described, but there is no uniformity of fact or opinion regarding the significance of this phenomenon or its relation to shock.

It is now clear that the observed differences in the circulatory response of man and animal were more apparent than real, since recent laboratory studies¹⁰ in the dog in which the maximum pulmonary ventilation compatible with the structural integrity of the lung was maintained for from one to fifteen hours established the fact that "acapnial shock," so called, is a phenomenon of narcosis. Furthermore, the changes in the circulation observed in the anesthetized dog cannot rightfully be termed shock when measured by the accepted standards for this condition, since the arterial hypotension is not progressive and does not significantly affect survival even though the condition may exist for many hours. It is evident that in some of the previously reported experiments trauma must have

played an important role. The evidence on which these statements are based is as follows:

No significant fall in the arterial pressure (greater than a few millimeters) occurs during excessive mechanical hyperventilation in the unanesthetized dog or during the recovery period from cyclopropane or pentothal anesthesia. The dog is therefore not basically different from man in its response to hyperventilation.

A decrease in arterial pressure, which varies from 10 to 50 per cent of the initial level, almost invariably occurs in the anesthetized dog during hyperventilation irrespective of the type of narcotic used. Furthermore, the degree of arterial hypotension is proportional to the depth of narcosis rather than to the magnitude of pulmonary ventilation. A gradual recovery of arterial pressure occurs during prolonged hyperventilation in the anesthetized dog, so that the original or a greater level is attained after several hours. Fatal circulatory failure during hyperventilation occurred only once in eighty dogs, this animal having a chronically enlarged heart with numerous mitral vegetations. Fatal respiratory failure did not occur in a single animal in this series unless ventilation was so severe as to result in rupture of the lung or in those experiments in which a large quantity of narcotic was purposefully administered just prior to the discontinuance of hyperventilation. Arterial hypotension is not observed in the anesthetized dog during hyperventilation if rise in plasma pH is prevented by gastric perfusion of 0.35 per cent hydrochloric acid, even though arterial carbon dioxide tension may be reduced to 5 mm. of mercury. Anesthetized dogs permanently survive from six to eight hours of the most severe hyperventilation. Hyperventilation tetany does not occur in the anesthetized dog.

Since these experiments establish the fact that narcosis modifies significantly the cardiovascular and respiratory response to respiratory alkalosis in the dog,

Chart 1.—Hyperventilation with oxygen during cyclopropane anesthesia. S, systolic; D, diastolic arterial pressures; P, pulse; solid block, hyperventilation; block with bars, apnea in minutes; encircled numbers, capillary blood samples; V_c, cell volume per cent; pH_s, plasma pH; (CO₂)_b, whole blood carbon dioxide content, volumes per cent; pCO₂, carbon dioxide tension, millimeters of mercury; (BHCO₃)_b, base bicarbonate, millimoles per liter of plasma.

it becomes pertinent to know whether such is the case in man. We have been unable to find any publications dealing with an experimental approach to this problem, although many of the functional disturbances which occur during or following anesthesia, e. g. circulatory failure and "fatal apnea,"¹¹ atelectasis and pneumonia¹²

and "ether spasm,"¹³ have been gratuitously ascribed to a reduction in carbon dioxide.

Whereas the large majority of all clinical administrations of narcotic drugs are associated with a respiratory acidosis from hypoventilation and the resulting carbon dioxide retention, there are certain circumstances in which hyperventilation may obtain. "Controlled respiration" is now a rather common practice of professional anesthetists. The tendency of novices

Chart 2.—Hyperventilation with oxygen during ether anesthesia. Legend as in chart 1.

when conducting artificial respiration is to hyperventilate the patient, particularly in emergencies.

The following experiments were therefore designed to study the functional effects of various grades of hyperventilation which might conceivably occur during anesthesia in man:

PROCEDURE

Patients of different age and sex with apparently normal cardiovascular and respiratory systems were selected who were to undergo short operative procedures. Data regarding pulse, arterial pressures and so on were obtained from the clinical record. When it was used, preliminary medication consisted of morphine sulfate and scopolamine hydrobromide in dosage appropriate to the age and condition of the patient. From one and one-half to two hours later, 0.5 to 1 cc. of capillary blood was obtained by finger incision, collected under oil and oxalated according to the procedure described by Shock and Hastings.¹⁴ This and subsequent samples were analyzed in duplicate by the microtechnique of these authors and the following information obtained: hematocrit (V_c); hydrogen ion concentration of plasma (pH_s) [determined at 38 C.]; carbon dioxide content of whole blood (CO₂)_b. Determinations of carbon dioxide were made by the method of Van Slyke and Neill.¹⁵ From these data the carbon dioxide tension (pCO₂) and the base bicarbonate (BHCO₃)_b were calculated by the equation of Hasselbalch as modified by Hastings and Shock.

Several pulse (half minute observations) and arterial pressure determinations (auscultatory) were made at

one minute intervals before anesthesia. A similar procedure was followed before, during and after hyperventilation. Anesthesia was induced in the supine position with ethyl ether, cyclopropane, tribromethanol 0.1 Gm. per kilogram, sodium amytal 0.01 Gm. per kilogram or morphine 0.08 Gm. and scopolamine 0.002 Gm. in divided doses. An orotracheal airway with cuff was inserted and the latter inflated. It was necessary to cocaine the pharynx and larynx when amytal, tribromethanol or morphine-scopolamine alone were used, in order that the orotracheal tube could be tolerated. The to and fro carbon dioxide absorption technic was employed with the canister placed close to the orotracheal tube to eliminate dead space. In addition to the agent, oxygen and small amounts of nitrogen completed the respired atmosphere except in one experiment in which air alone was used. When anesthesia had been established in a given plane, a second sample of capillary blood was obtained.

Hyperventilation was induced by two operators who alternately produced pressure on the breathing bag and pressure on the chest. The movements of both operators were rhythmic and all pressure changes were developed gradually rather than abruptly. The ventilation rates varied from 16 to 35 per minute. The intrapulmonic pressure developed at inspiration was not accurately determined but the maximum bag pressure varied from 20 to 30 mm. of mercury. An attempt was made to maintain a reasonably constant level of anesthesia (first or second plane) during hyperventilation with ether and cyclopropane, as judged by extrarespiratory signs. This objective was obtained in most instances, but if it varied the depth of anesthesia was decreased rather than increased. The arterial blood content of cyclopropane in one experiment, for example, was 6.9 volumes per cent at the beginning and 4.3 volumes per cent after fifteen minutes of hyperventilation.

The patients were observed closely during the periods of hyperventilation for signs of tetany. A sample of capillary blood was taken just before hyperventilation

had been completed in order to insure a more complete saturation and better equilibrium with the gaseous agents.

RESULTS

Hyperventilation of from eleven to twenty-one minutes' duration was produced in eleven patients. The degree of ventilation in some instances was as intense as could be obtained safely by manual methods. With the technical procedure employed it was impossible to

Chart 4.—Hyperventilation with oxygen during tribromethanol anesthesia. Legend as in chart 3.

determine the actual minute volume ventilation. The effectiveness of ventilation was determined entirely by the results of blood analysis. In two experiments, for example, the tension of carbon dioxide in arterial plasma was reduced to 9 and 10 mm. and the pH_s increased to 7.73 and 7.71, respectively. A summary of the results obtained and a characterization of the acid-base displacements are presented in the accompanying tables.

Arterial Pressure.—Systolic: The character of the changes in systolic pressure during anesthesia with different agents will be noted in the charts. The fall is not precipitate as in the experiments on animals, probably because of differences in the intensity of hyperventilation. The slow decrease argues against a mechanical interference with the pulmonary or coronary circulation as a major factor in the arterial hypotension. A casual glance at the curves of systolic pressure in the accompanying charts is apt to be misleading since the final systolic levels during hyperventilation are more readily compared with the elevated levels which obtained during anesthesia. If such a comparison is made, a significant decrease in pressure will be noted in nearly every case, ranging from 2 to 60 mm. and averaging 25 mm. A comparison of the final systolic pressures during hyperventilation with the normal resting values taken before premedication or anesthesia (projected in the figures as the dotted lines) indicates, however, that the change in pressure is much less significant than the former method of comparison would indicate. On the latter basis of comparison, the mean fall with hyperventilation was only 10 mm., the range varying from a rise of 8 mm. to a fall of 25 mm. In no instance did the systolic pressure fall below an absolute value of 92 mm. The skin remained pink, dry and warm and there was no evidence of shock in any subject.

During apnea following hyperventilation, the systolic pressure increased rapidly during the first two minutes and more slowly thereafter until the original or a higher level was attained within a few minutes.

Diastolic: The diastolic pressure, as the systolic, is usually elevated during anesthesia, probably from the accompanying respiratory acidosis. When the final

Chart 3.—Hyperventilation with oxygen during sodium amytal anesthesia. Legend as in chart 1. M, muscular activity (see text).

was discontinued. The last few inflations were made with pure oxygen and the bag left half filled with this gas (the pressure did not exceed atmospheric). The chest was exposed and the bag, chest and abdomen were observed closely for the return of activity. With the first spontaneous respiratory movement, the duration of apnea was noted and a blood sample obtained. Observations at one minute intervals were continued for at least twenty minutes after hyperventilation was discontinued and at five minute intervals throughout the subsequent operative procedure. In two cases hyperventilation was performed after the operative procedure

diastolic pressures during hyperventilation are compared with the anesthesia levels it would appear as if respiratory alkalosis is usually associated with a fall in diastolic pressure, since this did occur in eight of the eleven cases. A slight rise occurred in the other three, but the mean for the group was a decrease of 10 mm. As with the systolic, comparisons based on the changes from the normal resting levels of diastolic

Chart 5.—Hyperventilation with air during tribromethanol anesthesia. Legend as in chart 1.

pressure lead to a different interpretation. Thus, the final diastolic levels, although reduced below the anesthesia levels in eight cases, still remain above the normal resting level in the majority of subjects. The change with hyperventilation varied from a decrease of 6 mm. to an increase of 16 mm., the average being an increase of 7 mm. These results indicate that narcosis of the grade induced in these experiments does not completely prevent the increase in the peripheral resistance which is known to occur in the normal subject during forced breathing.

When hyperventilation is discontinued, the recovery of diastolic and systolic pressures progresses rapidly and in a parallel manner. In some experiments the diastolic pressure increased to a level above the original and remained higher for several minutes after hyperventilation, although the systolic pressure was not elevated above the original level during the same period.

Pulse Pressure: The pulse pressure was uniformly reduced in these experiments but not below an absolute value of 20 mm., except during amylal anesthesia (chart 3). A reduction in pulse pressure is usually interpreted to indicate a diminished stroke volume. Norlin⁴ has shown that forced ventilation in the normal individual is associated with an increased cardiac output which is proportional, within reasonable limits, to the degree of overbreathing. Roome¹⁶ observed values for cardiac output of from 84 to 110 per cent of normal in the hyperventilated dog during anesthesia. Experimentally,¹⁷ it is known that alkalosis increases the tone and irritability of cardiac muscle. It is interesting to note that the larger reduction in pulse pressure occurred during anesthesia with ether (chart 2), amylal (chart 3) and morphine-scopolamine (chart 6). These agents are known to depress the peripheral vagus. The heart rate increase was also larger in these experiments. It is not improbable that the vagal influence modifies the direct effects of alkalosis on the heart and that its removal constitutes a disadvantage.

Heart Rate.—Norlin⁴ observed a uniform increase in pulse rate during forced breathing in the normal subject. No significant change in heart rate was associated with hyperventilation during cyclopropane anesthesia (chart 1), the average value during anesthesia in five cases being 65 and during hyperventilation 70. These slow rates are of vagal origin. A rise of from 20 to 40 beats per minute occurred during ether, tribromethanol and amylal anesthesia. Hyperventilation increased slightly the rapid rate which obtained during morphine-scopolamine narcosis. No arrhythmias were detected by palpation of peripheral arteries during hyperventilation.

The heart rate was usually reduced further or increased slightly in apnea during cyclopropane anesthesia. With the other agents, the rate decreased from the higher level attained during hyperventilation.

Respiration.—The duration of apnea following hyperventilation varied from five to nine minutes in nine subjects who were hyperventilated with oxygen during complete anesthesia. No cyanosis or other alarming signs were observed in any of these subjects before respiration was resumed. It is to be remembered that in these experiments the narcosis was not deeper than second or third plane surgical anesthesia. The long period of apnea is probably related in part to the effects of the anesthetic but in large measure to the fact that the stimulus of anoxia was lacking. Norlin⁴ found that the period of apnea in normal subjects, even after vigorous hyperpnea with air for one hour, was only fifteen to twenty seconds. The results presented here cannot be compared directly with his, however, since the duration of ventilation is different. It has been observed in the dog that the period of apnea becomes shorter as the duration of ventilation is prolonged. Apnea is greatly prolonged in the normal subject if hyperventilation is accomplished with oxygen.¹⁸

The influence of oxygen can be observed readily in two experiments with tribromethanol anesthesia, in

Chart 6.—Hyperventilation with oxygen during morphine-scopolamine narcosis. Legend as for chart 3.

which patient 9 (chart 4) was hyperventilated with oxygen and patient 10 (chart 5) with air. Although apnea lasted eight minutes without cyanosis in patient 9, moderate cyanosis was observed during the ninety-second apnea in patient 10. It is interesting to compare the levels of P_{H_2} and the carbon dioxide at which

breathing was resumed in these two cases. In patient 9 both the pH_s and the carbon dioxide content had returned to the levels which obtained before hyperventilation. In patient 10, breathing began while the carbon dioxide content was still 12 volumes per cent below the level present before hyperventilation. It was not possible to calculate accurately the carbon dioxide tension or the base bicarbonate in this experiment because of the oxygen unsaturation of hemoglobin.

In one experiment during morphine-scopolamine narcosis, the period of apnea was only eight seconds although the subject had been hyperventilated with oxygen for twenty-one minutes. This remarkable difference is difficult to explain except on the basis of a scopolamine effect. It cannot be denied that scopolamine exerts an antidotal action on the respiratory effects of morphine in man.¹⁹ It is difficult to believe that such a short period of respiratory arrest would have occurred after 80 mg. of morphine without scopolamine, although the final answer will await experiment. It must be presumed on theoretic grounds that the oxygen delivery to the tissues is reduced in these experiments because of the known shift in the oxygen dissociation curve with alkalosis. It is improbable, however, that tissue anoxia served as the stimulus to breathing in the case with morphine-scopolamine any more than in the experiments involving other agents. Since anoxemia was absent, it is difficult to invoke carotid body stimulation to account for the short apnea in this subject. It is of interest to compare the levels of carbon dioxide and pH_s at which the first breath occurred with the level immediately preceding hyperventilation (table 2). The close similarity in values is striking except in patients 10 and 11. These results indicate further that an anoxic stimulus to respiration was absent in most of the experiments.

At the termination of hyperventilation, the chest was allowed to assume its own position. Whereas this position is the expiratory one and the accessory muscles are relaxed, it is not the type of chest observed with complete intercostal nerve paralysis due to the action of a narcotic drug. The intercostal muscles still retained their tone, and at the first inspiratory effort these muscles, as well as those of the diaphragm, were involved in the respiratory act.

Tetany.—The duration of hyperventilation was similar, and the degree of acid-base displacement was of the same order, or even slightly greater, than that obtained by Shock and Hastings²⁰ during voluntary hyperpnea in man. All of their six subjects but one exhibited tetany. Numerous observers have reported tetany following hyperpnea, whether induced voluntarily²¹ or as a result of anxiety states or disease.²² Tetany or muscle movement did not accompany hyperventilation during cyclopropane or ether anesthesia. Evidently the depressant effects of these narcotics are sufficient to prevent entirely the increased muscular activity.

Although the characteristic tetany was not observed, flexion of the thighs on the trunk occurred, a Babinski

reflex was present, and tendon reflexes were exaggerated during hyperventilation with tribromethanol anesthesia. During anytal anesthesia, hyperventilation induced flexion of the legs and fingers although the patient was in third plane anesthesia as judged by respiratory signs, preceding and following hyperventilation. During morphine-scopolamine narcosis, movements of large muscle groups and rigidity of the limbs were noted. The patellar and triceps reflexes were exaggerated and a Babinski reflex was present. When muscular activity was present during hyperventilation, it was invariably associated with a rise in both systolic and diastolic arterial pressures. This rise was sustained for several minutes. One subject vomited during very light cyclopropane anesthesia after eight minutes of ventilation. The arterial pressure immediately rose to levels considerably above the original.

All of the agents used in these experiments, with the exception of morphine-scopolamine, prevent the tetany of alkalosis. This observation casts doubt on the concept that respiratory alkalosis is an etiologic factor of significance in "ether spasm" or general convulsions during deep anesthesia with ether or other agents.

Hematocrit.—Since hyperventilation was done with an atmosphere saturated with water vapor, the fluid loss during hyperventilation was probably small, and the hematocrit values should be of interest. Almost without exception there was a slight decrease in cell volume. Whereas this change is not large and may not be significant, the trend is indicated. These results differ from those of Shock and Hastings, who noted an increase in cell volume in the unanesthetized subject. Since their subjects were presumably losing water through the lungs, the blood concentration may possibly be accounted for on this basis. It is possible that oxygen played a role, since a slight rise occurred in patient 10, who was hyperventilated with air only.

Base Bicarbonate (alkali reserve).—The base bicarbonate was reduced significantly during hyperventilation. This is due in part to an appreciable increase in acid metabolites such as lactic acid²³ and the ketone bodies.²⁴ At the end of the period of apnea in these experiments (except the morphine-scopolamine case) the base bicarbonate had returned to the prehyperventilation values. If hyperventilation had been continued longer, a certain portion of the base would undoubtedly have been eliminated in the urine or lost to the tissues, and the recovery of the original level would probably have been slower. During ether anesthesia the elevation in plasma pH was not as great as that obtained in other experiments although the hyperventilation was equally severe. This may be due to a greater production of acid metabolites. In this experiment, values for base bicarbonate were not obtained since ether interferes with the analysis for carbon dioxide.

General Effects.—No untoward effects were observed as a result of these procedures. Some of the subjects hyperventilated during cyclopropane anesthesia were awake within five to ten minutes after resumption of spontaneous breathing. Films of the chest taken before and after hyperventilation during ether anesthesia were identical in clarity although the usual postoperative elevation of the diaphragm was noted. The post-

operative course was uneventful in all patients. Electrocardiographic records were taken at one minute intervals during hyperventilation and continuously during the period of apnea in patient 10. When hyperventilation was discontinued, the pulse rate was reduced within thirty seconds from 115 beats to 85 beats a minute. Two ventricular extrasystoles were noted at this time. These were the only arrhythmias which were observed and were probably of vagal origin. During hyperventilation the T wave disappeared. Barker, Shrader and Ronzoni²⁵ have described recently a flattening of the T wave during alkalosis from hyperventilation or alkali administration.

COMMENT

The results presented here do not lend support to a hypothesis of shock based on acapnia as originally defined. The term acapnia has been studiously avoided in the present discussion. While the word as originally used had a precise though limited meaning, it has come to be a term without definition, convenient in its vagueness for the designation of any state of decreased vitality. Henderson¹² says:

The most practical definition of acapnia is that of an acute condition involving disturbances and depression of various functions, all of which are relieved and restored to normal by the inhalation of carbon dioxide.

This is an unfortunate state of affairs, since by such a definition it is difficult to establish an adequate rationale for the therapeutic use of carbon dioxide. Although carbon dioxide in certain concentrations serves as a pharmacologic agent and stimulates specific groups of nerve cells, the deduction that the initial cause of the nerve cell depression is a "carbon dioxide deficit" is difficult to justify. It would be as logical to state that epilepsy is due to a deficit of phenobarbital, since the latter compound is effective in the treatment of this condition.

Narcotic drugs depress certain physiologic mechanisms which allow the non-narcotized individual to compensate, in part at least, for a rapidly induced respiratory alkalosis. The circulatory changes and general signs which occurred in these experiments were in no respect comparable to those of traumatic or surgical shock, although the rapidity and extent of carbon dioxide loss greatly exceeds that which is likely to occur in clinical practice. It appears to be reasonable to take the position that the adverse effects of respiratory alkalosis on the circulation or on the general vitality, even during anesthesia, have been overemphasized. When these observations are correlated with those from the literature, the apparent differences between the response to respiratory alkalosis of the dog and man no longer exist, since without narcosis, and in these experiments even during narcosis, a significant arterial hypotension does not occur. The experiments presented here were of relatively short duration. The results obtained are so similar to those obtained in the dog that it seems safe to infer that a gradual recovery of arterial pressure would have occurred with longer hyperventilation, and that a similar and immediate return to normal would have been observed when hyperventilation was discontinued.

SUMMARY

Eleven subjects were manually hyperventilated for periods of eleven to twenty-one minutes during anesthesia with different agents.

A marked respiratory alkalosis was developed, the average increase in plasma pH being 0.31 unit from anesthesia level and 0.25 unit above normal level.

The carbon dioxide tension in arterial blood was reduced, on the average, 21 mm. below the mean level during anesthesia and 31 mm. below the mean normal level before anesthesia.

Systolic and diastolic arterial pressures were reduced during hyperventilation from the elevated levels of anesthesia, the average decrease being 25 mm. systolic and 10 mm. diastolic. The decrease from the normal systolic levels before anesthesia, however, averaged only 10 mm., whereas the mean change in diastolic pressure was an increase of 7 mm. above the normal before anesthesia.

The initial arterial pressures were reestablished rapidly when hyperventilation was discontinued, and no adverse effects on the circulation or general condition of the patient followed hyperventilation.

The duration of apnea varied from five to nine minutes without accompanying cyanosis when hyperventilation was performed with oxygen. In one subject hyperventilated with air, apnea lasted one and one-half minutes and was accompanied by moderate cyanosis.

Cyclopropane and ether prevented entirely the tetany of alkalosis, whereas amytal, tribromethanol and morphine-scopolamine did not entirely prevent, but modified, the character of the muscular phenomena.

CONCLUSIONS

These data, when compared with the effects of voluntary hyperpnea in man and correlated with the results of carefully controlled mechanical hyperventilation of anesthetized and unanesthetized dogs, prove that the arterial hypotension due to the rapid removal of carbon dioxide is a phenomenon which obtains only during anesthesia. Furthermore, it is incorrect to classify this hypotension as surgical shock, since (a) the hypotension is not progressive, (b) recovery of arterial pressure occurs even during continued ventilation and, (c) when hyperventilation is discontinued, recovery is immediate.

ABSTRACT OF DISCUSSION

DR. HENRY K. BEECHER, Boston: This field, as the speaker has pointed out, is extremely confused. It is stated that "the two greatest errors in the use of carbon dioxide in anesthesia consist in attempts to superimpose a respiratory acidosis on an acidosis of metabolic origin, and its use in asphyxial states in which blood and tissue tension of carbon dioxide are already so high as to be at a depressant level." It must be granted that carbon dioxide unwisely used may produce toxic effects. The use of carbon dioxide by anesthetists occurs chiefly on two occasions: To promote induction and to speed up recovery. Occasionally patients are encountered who are slow to be anesthetized. The induction may be speeded up in two ways: By increasing the concentration of the anesthetic agent; this has obvious drawbacks. By increasing the respiratory minute volume by the use of carbon dioxide; this seems to be the more desirable alternative. The desirability of using carbon dioxide can be determined in a given case by a simple physiologic test: Suppose carbon dioxide is added to the inspired gases to the extent of 5 per cent for one minute. If the patient is in the critical condition described, the addition of the carbon dioxide should further depress him and it can then be stopped, without serious effect. If, on the contrary, the respiration is stimulated by the use of a low percentage of carbon dioxide is permissible for the few minutes required to complete the induction, for if a seriously high blood carbon dioxide level had existed, the respiratory stimulation would not have occurred. Hyperventilation leads to considerable circulatory disturbance. The safety of hyperventilation is questioned by their finding that one dog in eighty did have a fatal circulatory failure. Apparently

25. Barker, P. S.; Shrader, E. L., and Ronzoni, Ethel: Effects of Alkalosis and Acidosis on the Human Electrocardiogram, *Am. Heart J.* 17:169 (Feb.) 1939.

dog had a diseased heart. When one considers the ease with which cardiac disease can be overlooked in man, doesn't this at least offer a warning? "Controlled respiration," that is, the production of apnea and the placing of the respiration at the discretion of the anesthetist, removes one of the most valuable safeguards of the circulation. The gradual onset of respiratory failure and ultimate respiratory paralysis are of importance as warnings that the blood concentration of the anesthetic agent is getting too high for circulatory safety. These warnings are of importance for the expert and are indispensable for the less than expert. Ten cases seems too few to allow any certainty of conclusion as to the effects of hyperventilation under a specific anesthetic agent. This remark is emphasized when it is recalled that several anesthetic agents are concerned in the ten cases. This paper shows that in ten cases shock did not occur as a result of hyperventilation during anesthesia. It is a step toward the elimination of misconception as to the limits of usefulness of carbon dioxide.

DR. M. H. SEEVERS, Madison, Wis.: We are not advocating hyperventilation as a procedure in anesthesia; we have merely made an experimental attempt to establish whether or not hyperventilation, even to the maximum which can be obtained by ordinary clinical procedures, produces a shocklike state. If we may be allowed to draw an analogy with the effects on the dog, I might say that such a shocklike state does not occur in a dog even though hyperventilation is conducted for eight or ten hours. The animals recover after this period even though the pressure of carbon dioxide in arterial blood is maintained at as low as 8 mm. I think the deleterious effects of carbon dioxide loss on the cardiovascular system have been greatly over-emphasized.

AVITAMINOSIS OCCURRING IN DIABETIC PATIENTS UNDER INSULIN THERAPY

V. P. SYDENSTRICKER, M.D.

L. E. GEESLIN, M.D.

AND

J. W. WEAVER, M.D.

AUGUSTA, GA.

The frequent occurrence of glossitis and stomatitis in persons with diabetes is a matter of common knowledge. The usual explanation of such lesions, particularly when complicated by monilial or spirochetal infection, has been "lowered resistance" or "a toxic state" due to hyperglycemia. Since the type of glossitis and stomatitis usually seen in diabetes is in all respects similar to that seen in mild endemic pellagra or in acute pellagra secondary to parenteral nourishment with dextrose solutions, it seems probable that the cause may be an avitaminosis caused by abnormal carbohydrate metabolism. Three cases recently observed would seem to substantiate this hypothesis. In two instances, signs of avitaminosis developed when carbohydrate intake and insulin dosage were rapidly increased; in the third, signs of nicotinic acid and riboflavin deficiency were present on admission, disappeared for a short time under an abundant diet and small doses of insulin but recurred when the diet and the insulin were increased.

REPORT OF CASES

CASE 1.—L. S., a white woman aged 58, admitted to the hospital Jan. 10, 1939, was known to have diabetes and had been observed in an outdoor clinic and was well maintained over a long period on a diet containing 70 Gm. of protein, 70 Gm. of fat and 150 Gm. of carbohydrate with 45 units of protamine zinc insulin daily. Her present complaint was an abscess of the left side of the neck of one week's duration. She was admitted to the surgical service, where it was found

that she was well nourished and developed with an obvious deep infection of the left side of the neck. General physical examination was not important. The blood showed 9.2 Gm. of hemoglobin per hundred cubic centimeters and 4,100,000 erythrocytes and 8,400 leukocytes per cubic millimeter. The blood sugar was 200 mg. per hundred cubic centimeters. The urine showed large amounts of sugar and "2 plus" acetone. The diet and insulin that had sufficed for control were continued. The abscess was incised and drained on the day following admission and an attempt was made to control glycosuria and ketosis with added dextrose and insulin. Because the patient became disoriented and glossitis developed she was transferred to the medical service January 30. On transfer she was disoriented and actively delirious; the tongue was bright red and atrophic and it was thought that she had pellagra. Nicotinic acid was given intravenously, 200 mg. a day for seven days. During this time she became quite rational and the glossitis healed. Because of persistent hyperglycemia and glycosuria protamine zinc insulin was increased on February 6 to 50 units, on the 13th to 60 units and on the 18th to 65 units. On the 20th severe glossitis recurred, and on the following day ulceration was added to the fiery redness of the tongue. Nicotinic acid was given, 100 mg. daily by mouth from February 20; there was rapid resolution of glossitis and stomatitis and improvement in appetite. On the 26th it was noted that the tongue looked normal. On this day the diet was reduced to protein 40 Gm., fat 40 Gm. and carbohydrate 120 Gm., and protamine zinc insulin was reduced to 50 units. Nicotinic acid was discontinued. Improvement continued and on March 6 protamine zinc insulin was reduced to 40 units with good control of the diabetic symptoms. The patient has continued to be well controlled from the standpoint of her diabetes, and glossitis has not recurred.

CASE 2.—M. H., a white woman aged 67, admitted Jan. 30, 1939, complained of pain in the right hip joint. She was known to have had diabetes for ten years and had been well maintained on a diet containing protein 40 Gm., fat 70 Gm. and carbohydrate 100 Gm., with protamine zinc insulin 25 units daily. Three years ago she suffered a fracture of the right femur and had been ambulant on crutches since; a week before admission she fell again and thereafter was unable to use the right leg. Examination showed that she was well developed and slightly obese, with a second fracture of the right femur. She was slightly disoriented and there was some redness of the tongue. The blood showed 10.2 Gm. of hemoglobin per hundred cubic centimeters and 4,350,000 erythrocytes and 9,500 leukocytes per cubic millimeter. The blood sugar was 280 mg. per hundred cubic centimeters. The urine showed large amounts of sugar and acetone. She was given appropriate orthopedic treatment and continued on the same diet and dosage of insulin that had sufficed at home, but delirium continued and there was persistent hyperglycemia with glycosuria and ketosuria. February 7 she was transferred to the medical service, where it was found that the tongue was bright red and fissured and that diabetes was not controlled. Diet was continued as before and protamine zinc insulin was increased to 45 units a day. Nicotinic acid was given intravenously, 100 mg. a day on February 7, 8 and 9, with marked improvement in the mental state and of glossitis. Glycosuria and hyperglycemia persisted, and the dose of protamine zinc insulin was increased on February 13 to 50 units, on the 15th to 55 units and on the 18th to 65 units. On the 18th the tongue became fiery red and the patient was again disoriented, glossitis grew rapidly worse and delirium developed, requiring restraint. On the 20th nicotinic acid was given by mouth, 100 mg. daily. By February 24 there was some improvement in glossitis, and delirium had cleared so that the patient could go without restraint and sat up. Because glossitis persisted nicotinic acid was increased to 200 mg. a day on March 3, 300 mg. on the 5th and 400 mg. on the 7th. Following the last increment of nicotinic acid there was rapid paling of the tongue and some regeneration of papillae. Diabetes was entirely controlled by diet and the amount of insulin given and the patient was dismissed March 13.

CASE 3.—K. W., a white woman aged 58, admitted March 1, 1939, complained of an ulcer on the right great toe. Before admission it had been found that she had severe glycosuria and

ketosuria. She was slightly obese and well developed. There was edema of the ankles and feet. The mouth showed deep fissures at the commissures of the lips with slight reddening and desquamation of the mucocutaneous junctures. The tongue was red and atrophic. The heart was moderately enlarged with a soft systolic murmur at the mitral area and a much accentuated aortic second sound. The blood pressure was 176 systolic, 110 diastolic. There was moderate vaginitis with a seropurulent discharge. The blood contained 13.5 Gm. of hemoglobin per hundred cubic centimeters and 4,600,000 erythrocytes and 9,000 leukocytes per cubic millimeter. Blood sugar was 330 mg. per hundred cubic centimeters. The urine showed large amounts of sugar and a trace of acetone. The diet prescribed contained 50 Gm. of protein, 50 Gm. of fat and 150 Gm. of carbohydrate; 15 units of protamine zinc insulin was to be given each morning. Insulin was increased March 4 to 25 units and on the 6th to 40 units to control glycosuria and hyperglycemia. The tongue and labial lesions healed rapidly during the first three days of treatment so that on March 6 the fissures at the corners of the mouth were healed and the tongue was of normal color. March 9 there was sudden recurrence of the commissural fissures, which were extremely painful, and the tongue was again red and tender. March 11, 10 mg. of riboflavin was given intramuscularly and, because no improvement was noted by March 13, 25 mg. was given by the same route. By March 15 the fissures at the corners of the mouth were healed but the tongue remained very red and somewhat tender. Protamine zinc insulin was increased on March 17 to 50 units and the diet was augmented by 10 Gm. of protein and 20 Gm. of carbohydrate. On March 19 the rhagades reappeared and the tongue was more red and painful. Riboflavin was given by mouth, 20 mg. a day from March 19 to March 25. There was improvement in the cheilitis on March 24 and by the 27th the right corner of the mouth was entirely healed; the left remained slightly red. Nicotinic acid was begun on March 26, 100 mg. a day by mouth. The tongue was pink and of good texture by March 29 and the fissures at the left oral commissure persisted. It seems likely that the marginal stomatitis will recur.

COMMENT

Two patients with complications of diabetes developed clinical signs of pellagra when the carbohydrate content of the diet was increased, and added insulin was administered to assure utilization of the augmented diet. In both cases nicotinic acid controlled the glossitis and mental symptoms but when carbohydrate or insulin was again increased the symptoms recurred and were again relieved by nicotinic acid. One patient who probably had an inadequate diet at home showed evidence of both nicotinic acid and riboflavin deficiency on admission. On a therapeutic diet with small amounts of insulin, signs of avitaminosis disappeared but recurred promptly with increase in the dose of insulin. Riboflavin given intramuscularly seemed to cure cheilitis but there was a prompt relapse after insulin was increased. Riboflavin and nicotinic acid seemed to cause much improvement in the signs and symptoms of avitaminosis. It would seem likely that rapid metabolism of carbohydrate such as is secured in diabetic patients by the use of insulin causes correspondingly rapid depletion of coenzymes and may in this way produce signs and symptoms of avitaminosis. There is at present no adequate explanation of the occurrence of avitaminosis under such conditions except that suggested. Since the diets given these patients were adequate in all vitamins, the question of inadequate absorption or storage must be given consideration. More important would seem the fact that coenzymes I and II both contain nicotinic acid, and it is quite possible that the great increase in dextrose metabolism caused by relatively large amounts of insulin might exhaust the body stores of this vitamin. The results of vitamin therapy in the cases under consideration would seem to confirm this hypothesis.

Since this report has been in preparation, observations have been published indicating that coenzymes are much depleted in diabetic patients with severe ketosis.¹ The experience of these authors in this work would seem to corroborate the conclusions that we have reached. Severe ketosis may follow exhaustion of coenzymes and logically might be expected to do so. Under chronic conditions, signs of avitaminosis might be expected to appear, with or without ketosis, when unusually rapid dextrose metabolism is brought about by the use of insulin.

HYPOSPADIAS

OBSERVATIONS ON ITS SURGICAL CORRECTION

CHARLES MORGAN MCKENNA, M.D.

CHICAGO

The best evidence that no standard operation for the correction of the hypospadiac deformity has been recognized by the surgical profession is the variety of methods employed by different men to achieve the same end result. It is obviously impossible in a short article such as this one to name all the authors who have contributed to this field, but one should mention Duplay,¹ Ombredanne,² Thiersch,³ Nové-Josserand,⁴ Bucknall⁵ and Beck⁶ among the older writers and Blair,⁷ Cabot,⁸ Cecil,⁹ Crabtree,¹⁰ Hagner,¹¹ O'Connor,¹² Lowsley,¹³ Higgins, Clinton Smith¹⁴ and Young¹⁵ among the later writers.

IMPORTANCE OF CORRECTING THE PENILE CURVATURE

There are two prominent features of every hypospadiac deformity: the defective urethra and the ventral curvature of the penis. There may be other associated pathologic changes such as undescended testicles, but the two conditions mentioned are found to some degree in every case.

My purpose in this paper is not so much to deal with the construction of a new urethra as to emphasize the necessity for correction of the curvature of the penis before attempting to form the new urethra. The amount of curvature of the penis varies in different

HYPOSPADIAS—McKENNA

2139

cases, usually being most marked when the urethral opening is farthest from the glans, that is, the perineal type. According to some authors this curvature is due to a thickening and contraction of Buck's fascia, while others contend that it is due to a lack of development of the corpus spongiosum, since there is no urethra present. Whatever the exact cause, a firm inelastic cord is present on the ventral surface of the penis which, as the corpora cavernosa develop, tends to pull the distal end of the penis downward and inward, curving it as a bow-string bends a bow. As the corpora cavernosa lengthen during erection, the curvature is of course much exaggerated, causing the penis to assume the shape of an inverted U.

Sometimes the shortening is not sufficiently marked to cause curving when the penis is flaccid but on erection a curve or crook appears. Sometimes the urethral opening may be quite close to its normal location and the possibility of this curving on erection is not thought of. It is a point that must be exactly determined before any plan of procedure is formulated.

When one reviews the literature, including the textbooks, it is interesting to note how little attention is given to correction of the deformity as compared to the enormous space given over to discussion of the

worse than before the operation had been done. The patients were little if any better off than they were before the surgical intervention. Uncritical examination of these cases would lead one to believe that they were good end results and probably were so considered by the surgeons responsible. The adult patients, however, felt otherwise.

OPTIMAL AGE FOR OPERATION

I believe that age is an important factor in the results in this work. In my experience, from 12 to 14 years seems to be the proper time to begin. However, I have seen children who at 11 years and occasionally earlier had genitalia and sex characteristics as well developed as those of a child of 14. Therefore the individual conditions present in any case govern the decision as to the optimal time for surgery. The younger the child, the more difficult the operation, because the parts are small and less easily managed. In cases in which the tunnel graft method is used to correct the curvature it may be performed when the boy is from 8 to 10 years old and the urethral reconstruction postponed a few years.

TESTOSTERONE AS A PREOPERATIVE MEASURE

In a number of cases we have used testosterone propionate (perandren) judiciously. When the genitalia are small and the urethral opening is far back in the perineum, the use of testosterone propionate may be

Fig. 1.—Technic of Hagner's tunnel graft method for correction of the ventral curvature. A, donor site for the graft; B, forming the graft into a tube about the trocar; C, tubular grafts in place; D, opening the tubular grafts at the second stage; E, tubular grafts opened out, adding to the length of the ventral surface of the penis.

methods of urethral reconstruction. The penis serves two purposes: it is primarily an organ of copulation and only secondarily, however conveniently, a drain for the bladder. Therefore in the surgical correction of hypospadiac deformities both these functions must be kept in view, and in the order of their relative importance.

Too often the construction of the urethra is the only phase thought of, or else the correction of the curvature is considered a minor preliminary to the urethral plastic operation and is given scant care and attention. In our clinic at the Illinois Research and Educational Hospitals we have seen many patients who had had good anatomic reconstructions of the urethra elsewhere but in whom good functional results had not been achieved. This was due to the fact that, while the urethra came to the end of the penis, the urethra was so short that some still had to sit down to urinate, and even those who could urinate standing found normal erection impossible. Some patients said that the curvature was

indicated. It not only develops the genitalia but tends to bring the urethral opening forward, both of which results simplify the construction of the new urethra. Often a hypospadiac child of 14 years will have genital organs of a size normal for a child of 7 or 8 years. The value of the intelligent use of this drug in these cases should be emphasized.

THE TUNNEL GRAFT METHOD OF HAGNER

Correction of the Deformity.—My first work on the correction of the downward curvature was patterned after the tunnel graft method of Francis Hagner. It was in most cases satisfactory but it necessitated at least two operations before the desired correction was obtained. As many as four tunnel grafts were sometimes necessary to accomplish the desired correction and obtain a penis that was straight when in erection. Some of the grafts were less satisfactory than others, owing to the amount of slough and the time before the denuded area was epithelized.

Dr. Vincent J. O'Connor and I, independently of each other, began using the tunnel graft at about the same time. We have operated on about the same number of patients with this method and a comparison of our results show that they are equally satisfactory.

The Hagner Technic.—This method utilizes free whole-thickness grafts of hair-free skin. As stated, this work may be done a little earlier than the urethral construction, depending on the size of the penis. An attempt is made before the time of operation to estimate the number of grafts that will be necessary. Each tunnel graft should add from 1 to 1.5 cm. to the length of the ventral surface of the penis.

An area on the thigh is selected which is as hair free as possible (fig. 1 A). A 16 F. trocar is used to introduce the grafts, and the size of the graft is determined by wrapping gutta-percha or metal foil around the trocar and cutting a pattern of the proper size. A

it is probably best to introduce only two at one sitting and do the others later.

The graft is left in place about three weeks. Then the tube is opened out by making a transverse incision

Fig. 2.—Transverse incision for dissection of the fibrous tissue.

piece of skin the size of the pattern is then dissected up from the donor site previously selected. In the original Hagner work some fat was lifted with the skin. We remove the skin with as little subcutaneous tissue as possible and it has proved more advantageous.

The skin graft is then wrapped around the trocar with the cutaneous surface inside and the edges sutured together with interrupted sutures of fine chromic catgut (fig. 1 B). In this way a tube of skin is formed. The trocar carrying the graft is then pushed transversely through the penis beneath the fibrous cord on the ventral surface. It is necessary to make a small incision on each side of the penis at the points of entrance and exit of the trocar. The tubular graft is so oriented that the suture line is nearest the ventral surface of the penis. The trocar is then removed and the ends of the tube are sutured to the edges of the cutaneous incisions on each side with a few interrupted silk sutures. A piece of silkworm gut is threaded through the tunnel and left in a large loop to keep the opening clear for drainage of any blood or serum that might otherwise collect (fig. 1 C). When more than two tunnel grafts are necessary

Fig. 3.—Large defect after fibrous tissue has been removed at the site of the pedicle graft.

through all the tissues between the tube and the ventral surface of the penis (fig. 1 D). The raw edges are sutured and the penis is bandaged in hyperextension

Fig. 4.—Pedicle graft swung in place and sutured.

and kept so until healing is complete. When these tunnels are opened the fibrous cord is cut and an epithelialized area equal in length to the circumference of the tube is added to the ventral surface of the penis (fig. 1 E). All of our cases in which the tunnel graft technic

was employed were successful except one. In that case three grafts were used. One sloughed out to such an extent that it was necessary to put in another graft.

PEDICLE GRAFT TECHNIC

Because of the multiple operations sometimes necessary we devised a new technic; at least it was new to us. A transverse incision was made on the ventral surface of the penis and the contracted fibrous tissue was carefully dissected out down to the corpora cavernosa (fig. 2). This left a large skin defect about 2.5 cm. wide by 2 cm. in length (fig. 3). This was a rather large area to cover by drawing the skin together from the sides as in the classic method which is advocated by almost every author except Hagner and Smith. Large tension relieving Heineke-Mikulicz incisions would be necessary on the dorsum of the penis, and these would shorten the foreskin so much as to make it practically

RECONSTRUCTION OF THE URETHRA

As stated at the beginning of this paper, it is not my purpose to dwell on this aspect of the problem of reconstruction of the urethra but merely to emphasize a few points which I have found most important. The correction of the curvature should always be done first and a sufficient length of time allowed to intervene before any work is done on the urethra. This is necessary to determine whether the result is satisfactory or not. If it is not, further corrective measures can be taken. Never should the urethral plastic operation be attempted at the same sitting as the correction of the curvature. What appears to be an adequate correction of the curvature at the operating table may prove afterward to be woefully inadequate. Also it has happened that surgeons purposely avoided correcting the curvature because in so doing the urethral deformity would be increased and the urethral reconstruction made more difficult. A urethral meatus that is 2 cm. from the glans in the hypospadiac penis may

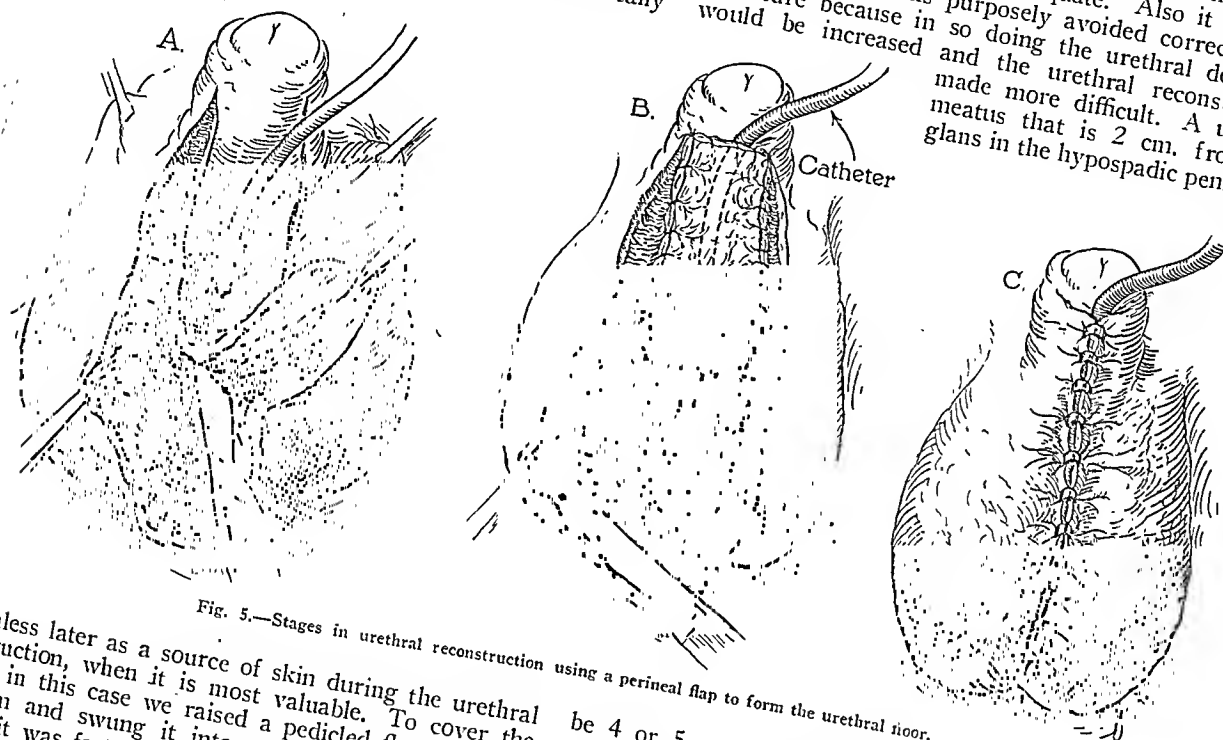

Fig. 5.—Stages in urethral reconstruction using a perineal flap to form the urethral floor.

worthless later as a source of skin during the urethral construction, when it is most valuable. To cover the defect in this case we raised a pedicled flap from the scrotum and swung it into position over the defect, where it was fastened in place by means of skin clips (fig. 4).

This technic has been successful every time I have used it. I have had one case since in which I reverted to the Hagner technic. The contracted fibrous tissue extended so deeply and seemed so firmly attached to the corpora cavernosa that I feared it would be impossible to dissect it free without too much injury to the corpora. I used the tubular grafts instead. Even when these have to be put through the corpora cavernosa themselves there are no bad after effects that I have seen.

In bringing the pedicle graft from the scrotum, as previously described, it is simple to make the graft wide enough so that the skin may be used in building the new urethra, as described by Smith.

The pedicle graft in my hands has been more simple and has required less hospitalization for the patient than any other technic I have used. The hospital stay is reduced to eight or ten days at the most.

be 4 or 5 cm. from the glans after the curvature is corrected. Obviously, such an attitude is inexcusable and should be heartily condemned.

DIVERSION OF THE URINARY STREAM

Diversion of the urinary stream, except by catheter in the immediate postoperative period, is not necessary during the operation for correction of the curvature. Any attempt at urethral reconstruction requires urinary diversion as an essential preliminary. I believe that suprapubic cystostomy is preferable in most cases because with it no urine gets beyond the internal sphincter into the urethra. There is no tube in the posterior urethra to cause the inevitable catheter urethritis and the possibility of contamination of the operative field with the resulting secretions or urine leaking around the tube. I have not tried Young's method of ligation of the bulbous urethra distal to the urethrotomy but I would expect it to be followed by stricture.

URETHRAL RECONSTRUCTION OPERATIONS

The number of different operations for the construction of the urethra is enormous. Which one is best suited in any certain case depends on the extent of the

urethral defect, the condition of the available tissues and the experience of the operator with the different methods. In the balanic type the foreskin may be buttonholed and is an excellent source of skin either for construction of the urethra or for covering of bare surfaces. In the penile type if the urethra is not too far back the foreskin is again available. The Ombrédanne operation is probably the most foolproof in the less severe penile types but has the objection of giving a bulbous rather than a tubular urethra and a much less satisfactory cosmetic result. In the perineal type I have used the method of Crabtree, in which the roof of the urethra is formed of penile skin and the floor of the proximal segment of the urethra is formed of a flap of skin from the perineum posterior to the meatus (fig. 5). A foreskin flap can be used to aid in building the distal segment. One should not try to make flaps too long. Recently I attempted correction of a cleft scrotum and made the perineal flap too long, with the result that a portion of the distal end sloughed. It is better to make the flaps in stages to permit good vascularization and avoid such occurrences. Lowsley's method of making the urethral tube in the perineum and then fastening the penis over it before severing the tube from its original bed assures a good blood supply.

HAIR FOLLICLE DESTRUCTION

There are a few other points to which I would call attention. Skin that is going to be used in the construction of the urethra must have all the hair destroyed. This means not only removed but the follicles destroyed. Older authors recommended surgical removal of the follicles. I refer all my cases to a dermatologist, who destroys the follicles by electrolysis. An interval should elapse to see whether there is any regrowth or new

Fig. 6.—End result in case of perineal hypospadias.

growth and if so that too must be destroyed. A perfectly formed urethral tube can be a constant source of annoyance if hair inside is constantly becoming encrusted.

THE USE OF SKIN CLIPS

Another point seldom emphasized is the use of skin clips on all external suture lines, especially in the urethral reconstruction. They do not have a tendency to cut through as do fine sutures if much edema occurs. They do not penetrate the skin and therefore do not leave a tract to predispose to the formation of fistulas.

Truly enough, they do not hold as well as sutures under tension, but in urethral plastic work there should be no tension. Tension is an invitation to failure.

PEDICLE FLAPS IN CLOSING FISTULAS

Despite all care, small fistulas will sometimes occur to mar an otherwise excellent result. They may delay repeated attempts at closure because the thinness of the tissues prevents suturing in more than two immediately adjacent layers with superimposed suture lines. In these cases, after the defect is closed in the urethral lining a pedicled flap from the scrotum can be used to cover the bare area. This prevents superimposing the suture lines. It was immediately successful in a case of mine in which several attempts had been made to close a persistent fistula in an otherwise good urethra which had been constructed elsewhere.

Fig. 7.—End result in case of penile hypospadias.

SUMMARY

1. In the operative correction of hypospadias, both the sexual and the urinary function of the penis must be given consideration.
2. Complete correction of the ventral curvature should precede any attempt to reconstruct a new urethra. Failure to do this may render valueless all later work.
3. The age at which this work is done depends on the size and development of the genitalia and must be decided individually in each case.
4. In those cases in which the scrotum and penis are small, the judicious use of testosterone propionate may be indicated.
5. The selection of the method for reconstructing the urethra depends on the conditions present. There is no "best" operation for all cases.
6. Diversion of the urinary stream, preferably by suprapubic cystostomy, should precede any attempt at urethral reconstruction.
7. Skin clips are preferable to sutures in all external lines of closure.
8. All hair follicles must be completely destroyed in those areas of skin used to form the urethral tube.
9. Tension must be absolutely avoided in all plastic procedures.

25 East Washington Street.

ABSTRACT OF DISCUSSION

DR. CLINTON K. SMITH, Kansas City, Mo.: The correction of the deformity seems such an obvious procedure that one wonders why it has received so little attention. I strongly suspect that the more fascinating part of the procedure, the plastic formation of a urethra, has overshadowed the less spectacular but nevertheless more important job of correcting the deformity. I should like to emphasize the importance of making an initial success of each successive step of the procedure. For instance, if a surgeon finds it necessary to reoperate to get sufficient correction of the deformity, he finds himself handicapped by the formation of scar tissue, which complicates the situation. I think that in this respect an overcorrection at the

time of the first sitting probably is one of the best forms of insurance. I like to have available at that time prepared skin grafts in order that, if it becomes necessary to denude the ventral penile surface, I can proceed with confidence, knowing that available material is at hand to cover the defect. These flaps should be attached without tension. In some of my earlier cases I had some discouraging experiences with sloughing skin grafts. I naturally fell into a plan of preparing skin grafts. This is done by taking up a section of skin on the scrotum or the foreskin and making a tube of it, allowing it to vascularize, and then later on detaching one end by slow constriction with a small rubber band. After the skin graft has been seasoned in this manner it can be manipulated with impunity, and one is practically 100 per cent certain that the graft is going to stick. There is one other point and that is the matter of the urethral opening, which is often of pinpoint caliber. This should be enlarged at the beginning and kept enlarged during the process, because in my experience the small opening, if left small, is productive of difficulty in the passing of sounds afterward.

DR. VINCENT J. O'CONOR, Chicago: The important point in the whole subject of hypospadias is rarely if ever mentioned. This is the necessity for proper correction of the penile deformity; as urologists, and therefore consultants in sexual matters, we see many persons who come to maturity with good plastic urethral construction but with an erect penile deformity which prevents intromission. It has occurred to me that the surgeon who performed the original corrective measure was either not aware of the importance of straightening the penis prior to remaking the urethra or else was interested only in the position of the urethral meatus. In my private practice I have seen sixteen patients who had so much penile deformity after a good reconstruction of the urethra done elsewhere that marriage was impossible. The severe deformities in these cases are the result of a thickening in the floor of Buck's fascia, and a simple dissection which merely frees the corpora cavernosa, as practiced by most surgeons, does not correct the deformity. The Hagner tunnel graft, which is placed directly through the corpora and permits ultimate incision of the thickened fascia, is the only method that will result in a correction of the severe type of deformity. As urologists who more keenly appreciate this problem, we should emphasize this most important point to those who operate on young boys at an age when this problem is not so apparent.

DR. VILRAY P. BLAIR, St. Louis: The principles of the plan that I have used for thirty years and modified from time to time contemplate three separate operative steps, or more when needed. The principles underlying the plan are: 1. (a) Release of the ventral or dorsal shortening by painstaking dissection and removal of the fibrous sheet that is closely adherent to the corpora cavernosa, the traction of which causes ventral bowing in the hypospadias or total shortening and weakened action of the vesical sphincter in the epispadias. (b) Immediate ample coverage of the resulting raw area with tissue drawn mesially from the body of the penis and pedicle flaps from the prepuce. It is from this covering that the lining of the new urethra will be constructed at the second step. 2. (a) Construction of the missing section of the pendulous urethra, either to the frenum or to the tip of the glans over a section of soft catheter of a size proportionate to the patient's age. (b) The resulting raw surface is immediately covered by a scrotal flap with a base much wider than its length. 3. The base of the scrotal flap is cut free, and the still remaining scrotal part of the urethral defect is closed. If done carefully on a patient who has not been circumcised, this procedure will give an anatomic restoration which is close to normal excepting that the new urethra will not be fixed to the corpora cavernosa. I believe that successful healing will depend largely on the following essentials: 1. Control of all bleeding by triple 0 silk ties. 2. Carefully placed superimposed deep and superficial rows of fine silk sutures in each suture line that insure deep approximation of flap edges. 3. Avoidance of superimposed suture lines. 4. Drainage by an indwelling catheter. I have discarded both cystostomy and urethrostomy in favor of indwelling catheter drainage, which I have found on the average to be the least of three evils. I

prefer that the latter remain in place from five to ten days. This is particularly desirable when the same catheter also supports the newly sutured urethra. 5. Choice of dressings. I rely chiefly on snug double spica-banded pressure dressings which splint the penis firmly against the abdomen or perineum to prevent accumulations of blood and control both infection and priapism, using gauze for wound protection and moist sea sponges for padding pressure. 6. Age of patient at operation. For the psychology of parents and patients I consider it a distinct advantage to complete the repair before puberty and have succeeded in doing this as early as 7 years. The hospitalization for the first step will average around one week and for the second and third steps, which are done with a minimum of an interval of three weeks, between ten and fourteen days each. An indefinite period elapses between the first and the second step.

DR. FREDERIC E. B. FOLEY, St. Paul: I will discuss only the problem of reconstructing the urethra. For many years I fussed with all the trick flaps, hair-bearing skin, prepuce and scrotum familiar to all of us. This was attended by all the difficulties referred to in Dr. McKenna's paper and in the previous discussion. Almost invariably it was a matter of four or five procedures, secondary closures of little fistulas, hair growing in the new urethra and so on. My results corresponded fairly well to other results and photographs which I have seen but not to the illustrator's drawings. For me the whole enterprise was beset with difficulty, and it was not a gratifying experience. A year ago Virgil Counseller called my attention to McIndoe's operation—a modification of the tube inlay graft of Nové-Josserand. I was aware of the original Nové-Josserand operation and of the fact that it gave very poor results owing to contraction and cicatrization of the inlay tube graft. McIndoe avoids this difficulty by keeping a removable mandril in the transplanted skin tube for several months. I tried the method. It has been a very gratifying experience. The operation for correcting the ventral curvature deformity should be done at an early age and repeated until a straight penis is obtained. The plastic operation to form the urethra must not be done until the penis is of near adult size. A special instrument is required. It consists of a metal tube size F. 24 and 10 or 12 cm. long. To one end of the tube is screwed a solid spear-pointed end; to the other end is screwed a handle. The spear-pointed end is pushed along under the skin of the ventral surface of the penis from the hypospadiac meatus to the glans, where it emerges in the position of a normal meatus. The spear-pointed end and handle are then unscrewed, the metal tube being left in the position of the new urethra. A thin sheet of skin cut from a non-hair bearing surface is wrapped around a catheter of size F. 20 or F. 22—"butter side out" of course—and is held in place with ties. This tube graft carried on the catheter is passed into the metal tube to the appropriate position. The metal tube is then withdrawn over the catheter, the tube graft being left in the grip of the surrounding structures. Ten days later the catheter is removed, the transplanted skin tube being left in place as a new urethra. For from eight to ten months the patient must wear an obturator in the newly formed urethra to prevent its contraction. A segment of soft rubber catheter serves this purpose well and causes no discomfort. At the end of this period the procedure is completed by anastomosing the hypospadiac meatus with the proximal end of the tube graft. By this method I have obtained by far the best result.

DR. CHARLES M. McKENNA, Chicago: The majority of patients suffering with hypospadias will sooner or later have an inferiority complex. This is usually true in any deformity of the genital organs. The patient should be encouraged rather than discouraged. Surgeons doing this type of work must be prepared for some grief, since the result will not be perfect in all cases. I think this should be explained to the family so that the impossible will not be expected in one sitting. Careful attention should be given to the blood supply to make a good result possible. When a graft is being made all tension should be relieved so that slough may be prevented. The technic is not the same on all patients. In other words, the fundamentals will be used but the technic will vary according to the type of deformity which confronts the surgeon.

Clinical Notes, Suggestions and New Instruments

STUDY OF A MALE CASTRATE

LAURENT FEINIER, M.D., AND THEODORE ROTHMAN, M.D., NEW YORK

Despite published evidence to the contrary, a rather common belief persists that complete castration of the adult male results in impotence.

For many years it has been known that the sexual impulse tends to continue in animals after castration. Sexual instinct and potency often persist in the ox and the gelding.

Havelock Ellis¹ reported that many castrated men continued to possess sexual impulses, as noted by medical observers in countries where eunuchism was produced and eunuchs were employed. McCartney² reported that ten of the twenty-three eunuchs examined by him showed gonorrhea. Osman and Schukru³ reported the continuation of sexual instincts and successful efforts in eunuchs. The earlier the age at which castration is performed the less marked the subsequent sexual desire, and the Chinese regarded boys castrated before the age of 10 as particularly pure and virginal.

Lange⁴ reviewed more than 300 cases of soldiers who had been castrated during the World War as a result of bullet wounds or tuberculosis. Of the 220 who were unmarried at the time of castration, 155 have married and "not a few did not notice any impairment of libido for many years and potency remained for a long time, although in a generally decreasing way." Kolle⁵ reported a series of fifty-eight surgically castrated men in at least a third of whom libido and potency appeared to be preserved. In contrast are the reports of de Quervain and Wolf⁶ at Berne and of Goll⁷ in Denmark, who reported consistent and almost entire suppression of libido and potency. The report from Berlin that a large proportion (possibly 30 to 50 per cent) of castrated criminals previously guilty of sexual offenses did not become repeaters is obviously open to psychiatric interpretation rather than complete acceptance on the basis of physical and hormonal mechanisms. Rowe and Lawrence⁸ reported a case of successful mental readjustment and sexual success in a surgically castrated man 25 years of age, whereas McCullagh and Renshaw⁷ reported loss of libido in nine of twelve adult male castrates.

Not unrarely, patients suffering from certain mental diseases seek and even demand castration and after the procedure may derive some temporary relief from mental conflicts and anxieties. Unwise and hazardous as such therapeutic procedure usually is, it is somewhat surprising to discover how frequently it has been rationalized and recommended by physicians. As Menninger⁸ has described, castration is even comparatively recently reported in the *Quarterly Cumulative Index Medicus* as a possible form of therapy for neurosis, perversions and sexual abnormalities, sexual crimes, mental diseases and tuberculosis.

The overemphasis which has been placed for so long on the gonads as the main source of potency and libido in males is certainly not in accord with general medical knowledge con-

cerning female castrates, who so often after surgical or x-ray procedure retain complete libido and ability for sexual responses.

Following is a report of long retention of sexual prowess in a surgically castrated man:

REPORT OF CASE

History.—A. I., aged 53, was admitted to the Vanderbilt Clinic because of severe periodic headaches occurring from twice a week to once a month, usually confined to one side of the head but often bitemporal and frontal and usually lasting from twelve to forty-eight hours. Either during or after the headaches, the patient was usually nauseated and vomited. The onset occurred thirty years previously, three to four months after complete orchidectomy for gonadal tuberculosis. One testicle was removed in a New York hospital and a few months later the other was removed in Naples, Italy.

At 7 years of age the patient had a convulsion without known cause. In the next year and a half several other seizures occurred, following which there was no further recurrence. He was considered a "weak and sickly" child.

The patient's mother suffered headaches of a type similar to his own. A sister was operated on for trigeminal neuralgia. His maternal grandmother became psychotic during the latter part of her life.

Previous to the surgical castration thirty years before, the patient had sexual intercourse about once a month and considered his potency and prowess rather poor. Nevertheless, three children were born. Subsequent to the removal of the second testicle his libido and potency promptly became definitely increased and in the words of his wife, to whom he had been married four years, "he was like a newly married man." The patient stated that thereafter he enjoyed his marital relationship more thoroughly and robustly until the past six months, during which the periodic headaches became more severe and more frequent and he had intercourse about once a week. There was no ejaculation other than a "few drops of sticky fluid."

Physical Examination.—The patient was well nourished, weighing 179 pounds (81 Kg.), cooperative and fairly intelligent. The habitus was feminine, with increased fat distributed about the breasts, hips and abdomen. The mammary areas were definitely enlarged. Pubic hair distribution was of the feminine type. The eyebrows were rather heavy and prominent. There was no evidence of testicular tissue. The voice was soft and modulated. The patient was polite, modest and courteous, with at times a suggestion of effeminate mannerisms.

There was no evidence of organic involvement of the nervous system, mouth, heart, lungs or abdomen.

The genito-urinary consultant was Dr. Leonard Hallock. He found no testicular tissue. The prostate as felt by rectum was very small and flat, not unlike many prostates in normal persons with normal testicles. The evidence of atrophy of the prostate was in accord with the cases reported by McCullagh and Renshaw, as was also the comparatively normal size of the penis.

The endocrine consultant was Dr. Irving Pardee. The skin was smooth with a slightly yellowish tinge. It presented a scanty line of hair on being stroked. The hair growth throughout was scanty; a beard was present but not profuse. Pubic hair was transverse and scanty. There was no mammary development, only fat. There was no structural change in the body or change in the voice. Dr. Pardee stated that the retention of libido is not unusual in these cases; as it had been reported in the literature and seen in one of his cases. He felt that the headaches in the present case were characteristically pituitary in type and location, being bitemporal and frontal. Their onset after orchidectomy and the undoubted "proliferation of castration" and its counterpart in the castration cells of the pituitary linked up this syndrome.

Laboratory Examination.—The blood count was normal. Blood chemistry showed a urea nitrogen level of 11.4 mg. urea 24.4 mg. and sugar 96 mg. per hundred cubic centimeters.

The Wassermann reaction of the blood was negative. The dextrose tolerance values were 92, 102, 82, 96, 102, 112 and 62 mg. The basal metabolic rate, determined on three different occasions, was —13, —10 and —20 per cent.

The determination of the gonad stimulating factor called "prolan" was 4 plus on two occasions and subsequently negative on two occasions.

Dr. Hugh H. Darby of the Department of Biological Chemistry, Columbia University College of Physicians and Surgeons, found no evidence in the patient's urine of the presence of either testosterone or androsterone. The extract and concentrate from 3,000 cc. of the urine when injected into capons produced no comb growth.

X-ray examination showed a normal skull. The sella turcica did not show any abnormalities.

Psychologic and Neurologic Examination.—The Arthur tests showed that the patient's intelligence quotient was 80. His English vocabulary and educational background were limited. Responses to the Rorschach ink blots suggested a reasonably good intellectual endowment and a neurotic tendency.

Masculinity-femininity tests (Terman and Miles⁹) resulted in a suggestion of a slightly feminine type, but the trend was not considered significant, the patient's reactions being standardized at the more feminine end of the masculine range.

Some degree of neuropsychiatric hereditary background was noted in the family history. The patient was one of ten children and in childhood was apparently overprotected by too solicitous parents. As a result of his convulsive seizures he was refused admission to school and keenly felt his social isolation and situation of insecurity. At puberty he began autoerotic practices, which were continued through late adolescence. Later, minor difficulties were experienced in adjustment to work and to social life. His courtship and marriage were apparently normal and, although the subsequent weakness in heterosexual relationship might be interpreted as a result of neurotic mechanisms, it could be attributed to the tuberculosis of the testicles. Preoperatively the patient had considerable fear of castration. He had been told that complete loss of virility would result. However, he had a strong erection on the fourth day after the removal of his second testicle. His continued potency and the gain in weight, although the latter was largely contributed to by increased adiposity around his breasts and pelvic girdle, was followed by his explanation that he "was stronger and more of a man than ever before."

During hospitalization no discrepancies in his ward conduct were noted. He was affable, showed considerable innate intelligence, had a good sense of humor and showed considerable pride in his one time association as secretary to a famous male singer. His behavior showed none of the profound mental changes which Rowe¹⁰ has reported may occur in male castrates.

COMMENT

The rather abrupt increase in sexual activity and prowess in this patient following castration was probably favorably influenced to some extent by the removal of the tuberculous foci.

It is possible that a compensatory Don Juan reaction to a castration fear in a person of a neurotic type might have played a secondary part in his sexual rejuvenation, but it is believed that the patient's increase in libido and potency was a compensatory mechanism in his unconscious for his castration. Psychically he gained something because of the loss of his testicles. He believed that he had grown heavier and therefore stronger and had proved he was more of a man. This obviously was a form of rationalization on the patient's part, although the favorable physical and psychic results following the removal of the tuberculous foci can by no means be entirely

discounted in attempting an interpretation of his subsequent reactions. Subsequently his position as secretary to a famous singer served to improve and maintain his morale. In psychiatric summary, this patient resembled the six patients with eunuchoidism studied by Carmichael and Kenyon¹¹ in that he did not reveal any characteristic mental picture, which is in accord with the opinion of Löwenthal¹² (as mentioned by these authors) that the sexual defect is the one feature which eunuchoids share in common. It would appear that adult castrates may vary as widely in their personal reactions and mental adjustment to orchidectomy as do people in general to the various other difficulties in life.

The development of physical characteristics suggestive of eunuchism appeared directly dependent on the castration, the resultant lack of testis hormone or hormones and the subsequent endocrine imbalance. Admitting the possibility that there may have been some testis or testis-like hormone in the patient's food supply, the capon tests for male hormones gave negative results. Although he was not castrated until 23 years of age the patient's physique supports the view that adequate gonadal activity is not only necessary for reproductive function but may also, even as comparatively late as young adulthood, be necessary for the complete development and the full maintenance of normal physical characteristics.

The rather low basal metabolic rates are in accord with pathologic-anatomic data reported by Wagenseil¹³ and the reports on eunuchoids by Carmichael and Kenyon¹¹ and on castrates by McCullagh and Renshaw.⁷

Although the patient's mother suffered periodic headaches of a type somewhat similar to his own, the onset a few months after castration in this case supported an interpretation that he suffered a lack of gonadal secretion and its inhibitory effect on the anterior pituitary. The gonadotropic substance found on several occasions and the bitemporal and frontal location of the headaches also confirmed the indictment of the pituitary gland as a factor.

The therapeutic response to ergotamine tartrate and phenobarbital was satisfactory, with no occurrence of severe headache for three weeks, whereas before admission he had been having a severe attack about twice a week.

The patient's conduct and behavior reactions, although slightly suggestive of the feminine type, were not sufficiently so to permit any definite deductions or conclusions. His emotional instability and neurotic tendency appeared as a result of his sickly childhood and the overprotection he received from a too solicitous mother.

This case is of interest in connection with the reports in the literature which have described the therapeutic use and value of testicular extracts in male adult impotence. It suggests that such beneficial effects are the probable result of either a gonadal suppressive action on the pituitary or, in some instances, a favorable psychogenic reaction.

It appears that in the full-grown adult the only indispensable sexual function of the testes is that of procreation and that libido and potency are functions of and controlled by the pre-pituitary and the psychic centers.

After puberty and adolescence with the development of the male sexual characteristics, castration need not result in the loss of libido and potency, nor are prominent mental or physical changes a necessary aftermath. Retention of sexual power probably depends to a considerable extent on the subject's pre-operative mental characteristics, type of personality pattern and tendency either to resign himself passively to his sexual defect or else combatively to compensate for it. Neuropsychiatric supervision of these cases should be of considerable value in

directing the patient's mental readjustment to castration, and it is suggested that when possible such psychotherapy should be instituted preoperatively.

SUMMARY

A 53 year old surgically castrated man retained libido and prowess for thirty years after complete orchidectomy. The patient's physical habitus suggested the feminine distribution of fat and pubic hair. No physical change was noted in the size or appearance of the penis. Tests for testosterone and androsterone gave negative results. Shortly after castration, migraine attacks began and continued, being of a type and character suggesting an unbalanced pituitary hyperfunction.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

METAPHEN (See New and Nonofficial Remedies, 1939, page 328).

The following dosage form has been accepted:

Medipax Brand of Vaginal Tampon-Suppositories with Metaphen 1:2,000: A product devised to enable prolonged medication to the upper vaginal vault and cervical region by incorporating a metaphen medicated suppository together with a tampon on a single applicator.

Actions and Uses.—The suppository contains 2.25 mg. (0.0375 grain) of metaphen in 4.5 Gm. (75 grains) of glycerogelatin shaped for insertion. After insertion into the vagina the suppository melts at body temperature. The tampon which is contained in the applicator and is composed of surgical cotton $1\frac{1}{2}$ inches wide by $2\frac{3}{4}$ inches long is released by appropriate pressure on the sleeve of the applicator. The tampon swells by taking up moisture, thus holding the medication in contact with the desired parts. A cord is attached to the tampon for convenient removal.

Prepared by Allen Laboratories, Inc., New Brunswick, N. J.

MERTHIOLATE (See New and Nonofficial Remedies, 1939, p. 326).

The following dosage form has been accepted:

Medipax Brand of Vaginal Tampon-Suppositories with Merthiolate 1:2,000: A product devised to enable prolonged medication to the upper vaginal vault and cervical region by incorporating a merthiolate medicated suppository together with a tampon on a single applicator.

Actions and Uses.—The suppository contains 2.25 mg. (0.0375 grain) of merthiolate in 4.5 Gm. (75 grains) of glycerogelatin shaped for insertion. After insertion into the vagina the suppository melts at body temperature. The tampon, which is contained in the applicator and is composed of surgical cotton $1\frac{1}{2}$ inches wide by $2\frac{3}{4}$ inches long, is released by appropriate pressure on the sleeve of the applicator. The tampon swells by taking up moisture, thus holding the medication in contact with the desired parts. A cord is attached to the tampon for convenient removal.

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1939, p. 141).

The following dosage form has been accepted:

Ampuls Bismuth Subsalsicylate in Oil 0.13 Gm. (2 grains), 1 cc.: Each cubic centimeter contains bismuth subsalsicylate-U. S. P. 0.13 Gm. (2 grains) in sterile olive oil suspension containing 3 per cent chlorobutanol (chloroform derivative).

Prepared by the William S. Merrell Company, Cincinnati, Ohio. No U. S. patent or trademark.

LUMINAL SODIUM (See New and Nonofficial Remedies, 1939, p. 126).

The following dosage form has been accepted:

Luminal-Sodium Tablets, 1 grain.

MERCURIC SALICYLATE (See New and Nonofficial Remedies, 1939, p. 319).

The following dosage forms have been accepted:

Ampuls Mercury Salicylate in Oil 0.065 Gm. (1 grain), 1 cc.: Each cubic centimeter contains mercuric salicylate-U. S. P. 0.065 Gm. (1 grain) in sterile olive oil suspension containing 0.5 per cent quinine and urea hydrochloride-U. S. P.

Prepared by the William S. Merrell Company, Cincinnati, Ohio. No U. S. patent or trademark.

Ampuls Mercury Salicylate in Oil 0.1 Gm. (1½ grains), 1 cc.: Each cubic centimeter contains mercuric salicylate-U. S. P. 0.1 Gm. (1½ grains) in sterile olive oil suspension containing 0.5 per cent quinine and urea hydrochloride-U. S. P.

Prepared by the William S. Merrell Company, Cincinnati, Ohio. No U. S. patent or trademark.

Council on Foods

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT BY DR. COWGILL OF ONE OF THE TOPICS DISCUSSED WHEN CONSIDERATION WAS BEING GIVEN TO THE QUESTION OF THE DESIRABILITY OF ADDING VITAMIN B₁ TO FOODS. PARTLY ON THE BASIS OF THIS REPORT, THE COUNCIL HAS ADOPTED CERTAIN POLICIES WHICH HAVE BEEN REPORTED IN THE JOURNAL FOR AUG. 19, 1939.

FRANKLIN C. BING, Secretary.

THE NEED FOR THE ADDITION OF VITAMIN B₁ TO STAPLE AMERICAN FOODS

GEORGE R. COWGILL, PH.D.

NEW HAVEN, CONN.

The recent isolation and synthesis of vitamin B₁ (thiamin)¹ has placed in the hands of clinicians and students of nutrition alike a most valuable therapeutic agent as well as dietary essential in pure form. Clinical trial of this substance in the United States over a comparatively short period has already yielded results so striking as to warrant consideration of the question of the adequacy of American diets with respect to vitamin B₁. It has been generally recognized that the diets in common use in the Orient and certain other parts of the world where beriberi is endemic are seriously deficient in this factor, but until comparatively recently it has been questioned whether this is true also for the United States and European countries. The recent and remarkable successes attending the use of pure vitamin B₁, often in conditions in which lack of this factor seemed quite unlikely, can be interpreted only as meaning that vitamin B₁ deficiency must be much more widespread in this country than clinicians have believed hitherto. Strauss,² who has reviewed this recent therapeutic use of vitamin B₁, definitely states that "vitamin B₁ deficiency is probably more commonly found in the United States than has been supposed. The observations of Spies and his colleagues,³ who have been studying pellagra, are particularly interesting in this connection. In many of their cases in which nicotinic acid has been provided but the patients allowed to continue on their customary diets the symptoms of pellagra have been relieved but those of beriberi have eventually appeared, thus demonstrating the presence of a B₁ deficiency masked by a more serious shortage of nicotinic acid. Jolliffe⁴ has recently published a clinical evaluation of the adequacy of vitamin B₁ in the American diet. He concludes that the margin of safety against beriberi afforded by American diets "varies from 20 to 80 per cent," depending on the method used in making the evaluation. "A large fraction of our population, particularly those spending per capita less than two dollars per week for food, subsist on diets of borderline adequacy in vitamin B₁." Jolliffe also expresses the opinion that, "while vitamin B₁ deficiency is endemic in the United States, this disease, called beriberi in the Orient, is usually classified here under one of a variety of misleading diagnoses such as 'alcoholic,' 'gestational,' 'diabetic,' 'metabolic,' or 'gastrogenous' polyneuritis" (p. 65).

4. Jolliffe, Norman: A Clinical Evaluation of the Adequacy of Vitamin B₁ in the American Diet, Internat. Clin. **4**: 46-66 (Dec.) 1937.

To students of the physiology of vitamin B₁,⁵ these recent developments are by no means unexpected. The relation of minimum daily requirement to effective curative dose in animals, considered along with such estimations of the probable human requirement as it was possible to make in the absence of trials with the pure vitamin, suggested that with the concentrates available at the time it would be very difficult to demonstrate in any dramatic fashion the value of this vitamin in the treatment and prevention of the less striking features of the beriberi picture. Conservative interpretation of such clinical observations as were made with vitamin concentrates was doubtless to be expected.

The recent changing view of clinicians regarding the serious probability of vitamin B₁ deficiency in this country raises some interesting questions for all students of nutrition and public health. The solution of these questions is of great importance in relation to the general health and welfare of our people.

Let us first consider how much vitamin B₁ human beings should receive. From the data presented in a recent review of the literature bearing on this question⁶ it appears that adults require daily as a minimum approximately 300 to 350 international units (I. U.) of the vitamin, which is equivalent to about 1 mg. of the pure thiamin.⁷ This minimum is equal to about 10 international units per hundred calories daily. Preschool children apparently need as much as 20 to 25 or more international units per hundred calories daily. It is pertinent to consider to what extent these requirements are being met under the dietary conditions prevailing in the United States. If they are being met, what appears to be the factor of safety above these minima afforded by our American diets?

FOOD STATISTICS

In attempting to answer these questions, statistics of food consumption for the nation as a whole may be examined, particular attention being paid to those foods which are low in vitamin B₁ but used in relatively large amounts. The two most important foodstuffs in this connection are the cereals, with their refined products, and sugar.

Cereals constitute the principal source of energy in the world's diet, but the predominance of particular cereals over others in any given part of the world appears to be the resultant of a variety of factors, notably ease of cultivation, cost, purchasing power of the population, custom and taste. As is well known, rice is the staple cereal in the Far East, whereas wheat occupies the dominant position in the United States and Europe. For the years just before the Great War, it appears that the people of the United States secured about 34 per cent of their total calories from cereals; 26 per cent were derived from wheat, which constituted about 75 per cent of the total cereals used.⁸

In table 1 are presented data for consumption of wheat in the United States during certain periods.

From the review of data on world use of cereals prepared by the Mixed Committee of the League of Nations⁹ (see table 1) it is evident that there has

been a steady decline in the food use of bread cereals for a period of years, and this decline appears

to have been greatest in the countries where the great bulk of the cereal consumption consists of wheat. These are, in general, the countries with the highest levels of living; as income rose, there was a partial substitution of more expensive non-cereal foods for wheat. In countries where rye or maize was the principal cereal, there has, on the other hand, been a tendency towards their displacement by wheat [p. 102].

For a person with an average daily energy exchange of 3,000 calories, the wheat consumption for 1929-1934 (table 1) would mean approximately 32 per cent of the calories derived from this cereal. Assuming that the decline in consumption of cereals in the United States has continued to the present year, it does not seem unreasonable to conclude that our population, by and large, secures probably as much as 25 per cent of its calories from wheat and its many products.

Let us consider what this means with respect to intake of vitamin B₁. The roller mill for manufacture of wheat flour was invented by Helfenberger about 1830. The first American rolls to be constructed were installed in Connecticut about 1874. Prior to Helfenberger's

TABLE 1.—Consumption of Wheat and Cane Sugar

Food	Period	Consumption		Yielding About	
		Per Capita		Calo- ries per Day	Per Cent of 3,000 Calories Daily
		Per Year,	Per Day,		
Wheat (Wheat Studies of the Food Research Institute, Stanford Uni- versity, Calif. 11, No. 7, 12, No. 10, 1935)	1894-1899	145.6	399		
	1909-1914	140.2	384		
	1929-1934	100.2	274		
	1821	8.6	9.9	89	1.8
	1850	13.6	37.3	149	5.0
Cane sugar (1821, 1850, 1900 and 1928 Nutrition, ⁹ p. 108, 1931, Mendel, L. B.: J. A. M. A. 99: 117 [July 9] 1932)	1900	30.2	83.8	385	11.2
	1928	47.0	128.8	515	17.2
	1931	49.0	134.2	537	17.9

invention wheat flour was obtained by grinding between stones. According to Baker, Wright and Drummond¹⁰ such a flour represented 81.4 per cent of the original wheat kernel and contained on an average 1.65 international units of vitamin B₁ per gram and about 62 per cent of the total vitamin present in the wheat. In contrast to this, modern wheat flour represents only 72.5 per cent of the kernel and has as low as 0.15 international unit of vitamin B₁ per gram and only about 5.5 per cent of the vitamin originally contained in the cereal. In other words, the modern milling process gives us a product with a vitamin B₁ content about one eleventh of that of the old stone-ground flour. Such a change would not be of much practical importance if the products in question formed only a relatively small part of the dietary. When, however, they furnish as much as 25 or more per cent of the total calories consumed, this tremendous decrease in vitamin B₁ content becomes serious indeed.

Another well known component of the American dietary important in this connection is sugar. Table 1 presents data indicative of the consumption of this food in the United States over a period of years.

In contrast to the decreasing use of cereals there has been a steady rise in the consumption of the highly purified foodstuff cane sugar. No doubt this has been due in considerable measure to the great developments

5. Cowgill, G. R.: The Physiology of Vitamin B₁, J. A. M. A. 110: 805-812 (March 12) 1938.

in the sugar industry making the available supply greater than ever before, but the sweet taste of this product has also played a great role. That sugar is valuable as a source of energy cannot be questioned, but, to the extent that it displaces other foods which may at the same time function as carriers of important nutrients such as minerals and vitamins, this increasing use of sugar is obviously not in the public interest.

The statistical data presented in table 1 indicate that the American people secure something like 42 or more per cent of their calories from these two foodstuffs relatively poor in vitamin B₁ or free of it. The decreasing use of wheat, which is a fact to be considered, cannot be regarded as playing a significant helpful role in this connection, because it is more than offset by the increasing use of sugar. In the decades immediately after the introduction of modern milling processes there was still an appreciable demand for less highly refined wheat products. However, the more refined white flour has steadily gained in popularity because of its many advantages, notably its stability in commerce as contrasted with whole wheat flour, for example, and its whiteness with consequent appeal to the eye, suggestion of greater purity. This last named advantage (?) is similar to that possessed by polished rice, which has proved to be the favored cereal in the Far East in spite of numerous governmental efforts to secure widespread substitution of undermilled rice for it in the attempt to combat beriberi.

The foregoing summary of statistics on wheat and sugar suggests that these foods supply daily at least 42 per cent of the total calories. It will be noticed that I have taken 3,000 calories a day as the base of reference. If smaller figures, 2,700 or 2,500, for example, are used, the percentages become 55 and 60, respectively. If Swanson's treatise on "Wheat and Flour Quality"¹¹ is taken as the authority, the total calories obtained daily per capita from wheat and cane sugar represent about 1,375 calories. This constitutes 45 per cent of a 3,000 calorie total, and 51 and 55 per cent when the daily totals are 2,700 and 2,500 calories, respectively.

In commenting on the significance of these changes in food habits and the effects of milling on the wheat, Jolliffe aptly writes: "It seems, therefore, that a 55 per cent fraction of the calories in the American diet of 1840 containing a minimum of 600 I. U. of vitamin B₁ has been replaced in the contemporaneous American diet by a like fraction containing only about 50 I. U." (p. 52).

Students of nutrition now emphasize a greater use of the so-called "protective foods," which are primarily milk, green vegetables and fruits. These foods are excellent sources of calcium (milk and green vegetables) and vitamin C; however, they do not rate high in vitamin B₁ content. If the American people continue to use wheat and sugar in amounts currently consumed, simple calculation reveals that, in order to secure the 550 international units of vitamin B₁ which has been lost during the past century as a result of refinement in milling of wheat, one would be forced to consume tremendous and impossible quantities of these particular "protective foods." Taking the distribution of foods characteristic of the average American diet described by Sherman¹² as a basis of estimation, Jolliffe⁴ finds that one would have to consume daily a combination of 625

Gm. of fruit, 600 Gm. of potatoes, 880 Gm. of other vegetables and 1,260 cc. of milk. This combination is, of course, impossible because of its bulk. It might be supposed that there are many other foods which could be used to advantage here, but careful study of this point indicates that these "other foods" are rather limited. Thus, an examination of the lists given on pages 236-240 in tables X-XVI of the monograph by Williams and Spies¹³ indicates that only ten foods contain more than 3 micrograms of thiamin per gram of the food. In order to appreciate the significance of these figures, the reader should remember that whole wheat contains on an average about 4.6 micrograms per gram. A more liberal use of other seeds besides those of the cereal plants, notably nuts, and the members of the legume family, such as beans and peas, would constitute a partial solution of the problem. However, these foods are all of them quite concentrated with respect to energy and therefore can be used in this way only to the extent that they replace cereals and sugar. On the other hand, fruits, vegetables and milk, because of their high moisture content, must be ingested in considerable quantity in order to serve as noteworthy sources of calories. Another point is worthy of mention in this connection. Many of the foods that might be considered suffer some loss of the vitamin through poorer methods of preparation in the home, such as, for example, those which involve leaching out into the water used in cooking and then rejection of that water. The operation of this factor cannot be stated quantitatively, but obviously any consideration of it means that the public's intake of the vitamin may be even lower than the foregoing rough estimates.

The discussion thus far has been limited almost entirely to wheat and sugar, and it has been shown that no very satisfactory solution of the problem can be expected by efforts directed toward greater use of the "protective foods" other than whole grains or the germ. It seems unnecessary to belabor the point that, so far as food statistics indicate, the American dietary is not rich in vitamin B₁, as many people have supposed, but too close to the minimum in this respect to be viewed with equanimity.

AMERICAN DIETARIES

Statistical studies of food consumption such as have been discussed constitute only a first approximation answer to the question What do the people eat? More precise information must come from examination of food intake records. Fortunately, data of this sort are available for examination. Stiebeling and Phipard¹⁴ have made extensive analyses of the content, cost and nutritive adequacy of diets of employed wage earners and low salaried clerical workers in four sections of the United States, namely North Atlantic states, Pacific, East South Central and the South:

The study was based on about 4,000 records of a week's food consumption, placed at the disposal of the Bureau of Home Economics through the courtesy of the Cost of Living Division of the United States Bureau of Labor Statistics. The records were collected in 1934-37 as part of a study of income and disbursements for family living.

In their discussion of vitamin B₁, Stiebeling and Phipard state (p. 61):

The average vitamin B₁ content of the diets of these families shows a gradual increase with rising weekly expenditures for food. Expenditures of \$0.63-\$1.24 a person a week brought:

12. Sherman, H. C.: The Chemistry of Food and Nutrition, ed. 4, New York, Macmillan Company, 1932.

diets containing from 280 to 330 international units of vitamin B₁ a requirement unit a day, respectively, in the case of white and Negro families in Southern cities. Less than a tenth of the white families of these cities, but about one third of the Negro families, were spending these amounts for food. The average vitamin B₁ content of their diets was scarcely two thirds of the fairly liberal suggested allowance.

The general reader may desire some comment on the meaning of the term "requirement unit." When dealing with families and other groups instead of individuals, it is obviously desirable both to take account of the requirements of the various individuals in the family and to deal with the family as a unit. The "requirement unit" represents an attempt to deal with this situation. Thus, Stiebeling and Phipard defined their unit as the need of an adult 20 years and over in age, and this requirement was set at 500 international units of B₁ or 1.5 mg. of pure thiamin, and given a value of 1.0 on a requirement scale. For boys 16 to 19 years of age the corresponding figures taken are 600 international units and 1.8 mg., respectively, or a factor of 1.2 on the "requirement scale." For children of other ages the respective figures range downward to those for children under 4 years of age, namely 200 international units, and 0.6 mg., and a factor on the requirement scale of only 0.4. A family consisting of both parents, a 16 year old boy and a 3 year old child would then require 2 plus 1.2 plus 0.4 or a total of 3.6 times the unit requirement, which would be equal to 1,800 units. This could also be expressed as 1,800 units divided by 3.6 requirement units to give "500 units a requirement unit." On this latter basis families can be compared, with the needs of the individual members also given their due consideration.

Another quotation much to the point is the following (p. 63):

Of the entire number of white families participating in this survey, it is estimated that the 25 per cent choosing diets lowest in vitamin B₁ obtained less than 400 international units a requirement unit daily and 75 per cent, 600 or less international units a requirement unit a day. About 10 per cent selected foods furnishing less than 300 international units a requirement unit a day, and about half of the families obtained 500 or more international units of vitamin B₁ a requirement unit a day. . . .

There is probably little danger of serious vitamin B₁ deficiencies if individuals *regularly select*¹⁵ a goodly share of their needed calories from foods that have not been artificially refined or depleted of their vitamin B₁ by the processes of preparation. The relatively high vitamin B₁ value of diets of Southern Negro families, even when weekly food expenditures were low, was due to the fact that they consumed large quantities of whole corn meal, sweet potatoes and pork.

The words I have italicized should be emphasized in this connection because they really mean here that the factor of safety against vitamin B₁ shortage is not large: that these families in question must pay special attention to the matter of proper choice of foods if they are to obtain sufficient quantities of the vitamin. When particular attention must be paid to this matter, success will be determined in considerable measure by the knowledge of vitamin B₁ distribution in foods and the like which the families possess. Although we may pride ourselves on the high literacy rate characteristic of the American people by and large, we cannot but feel most dissatisfied with respect to the possession of detailed knowledge of food values on the part of the great mass of our population.

15. Italics are mine.

Jolliffe⁴ has evaluated these Stiebeling-Phipard dietaries for vitamin B₁ content in two ways and estimated their respective factors of safety against vitamin deficiency. Using my vitamin/calory ratio as the criterion, the average of his calculations of the factor of safety afforded by these particular dietaries proves to be 14.4 per cent, with three of the eighteen groups yielding negative instead of positive values. When the Williams-Spies¹³ thiamin/non-fat calories ratio is used as the basis of judgment, the average proves to be 18.3 per cent, with one group giving a negative value. It is unnecessary to discuss here the relative merits of the two modes of calculation employed, especially when they yield results so nearly the same. Let it suffice to call attention to the fact that these averages are not much above the average variations encountered in numerous biologic phenomena, such as, for example, basal metabolic rate. If, then, these American dietaries, the best averaged in with the poorer ones, afford a factor of safety against vitamin B₁ deficiency only moderately above what is estimated to be the requirement of normal healthy people, and the effects of diarrhea¹⁶ and other fairly common conditions in increasing the amount of vitamin needed are also taken into account, one cannot fail to be impressed with the importance of considering measures for increasing the vitamin B₁ content of American foods. Additional evidence may be reported in support of the idea that many of our American dietaries are not optimal in content of vitamin B₁. Thus, Morgan and Barry¹⁷ were able to show that the addition of B₁ rich materials to the diet of school children was associated with a definite increase in the growth rate; Summerfeldt,¹⁸ and Ross and Summerfeldt¹⁹ have also reported that the addition of vitamin B₁ containing materials to presumably adequate dietaries for children resulted in more rapid growth and improved nutritional status.

In all probability the present shortcomings of American dietaries with respect to vitamin B₁ content have not developed suddenly but are the result of a gradual change proceeding over a period of years. The food statistics that have been reviewed indicate that the per capita consumption of sugar has grown steadily for a century and has remained fairly uniform at a high level for only a few years. Such an increase has undoubtedly operated gradually to diminish the vitamin B₁ of our dietaries. The effect of the developments in wheat milling has been most pronounced since about 1870, with the highly refined wheat flour steadily gaining in use and popularity. I have not been able as yet to secure suitable American data on which to base calculations expressing more precisely this downward trend in B₁ content of dietaries in the United States. However, the conditions in this country have probably been fairly similar to those in England, particularly as affected by the growth of the sugar industry and the changes in the milling of cereals, the two dominant factors under consideration. Baker, Wright and Drummond²⁰ have made estimations of the probable B₁ content of various English diets used as far back as 1615. Table 2 is taken from their paper.

It will be noticed that about a hundred years ago (1838) there was some variation with respect to dietaries used in feeding the poor. The Poor Law applicable to the city of London provided a better diet as regards vitamin B₁ than that in force in Dudley Union. The most striking fact of interest in this connection is the observation that the paupers fed under the Poor Law of London in 1838 received approximately twice as much vitamin B₁ as the two highest income groups of London studied in 1937. It is difficult to escape the conclusion that the trend of vitamin B₁ supply over the past century has been definitely downward. If this condition is not now recognized and then made the basis of appropriate action, we may confidently expect to see our population as a whole in the same category as the masses of the Far East, where polished rice is the favored staple used in too great amounts with the consequence of a high average incidence of manifest beriberi. As was pointed out earlier in this paper, many clinicians have already convinced themselves that a dangerous situation in this respect has been reached.

PRACTICAL MEASURES

If the thesis is accepted that current American dietaries are not satisfactory in content of vitamin B₁, the question arises as to what practical measures might

TABLE 2.—Probable B₁ Content of Various English Diets

Date	Diet	Vitamin B ₁ Yielded per Day, I. U.
1615	Suggested diet for seamen.....	640
1670	Soldiers' ration	1,000
1686	Patients in Barts.....	300-700
1782	Parish poor	600-850
1830	Diet of John Dalton.....	1,230
1836	Prisoners, Ipswich prison.....	700
1838	Poor Law, city of London.....	1,060
1838	Poor Law, Dudley Union.....	600
1937	London dietaries: two highest income groups*..	450-550

* Cited by Baker, Wright and Drummond¹⁰ as "Lloyd's data."

be taken to improve them in this respect. It seems unquestioned that we should continue to employ the educational process in every possible way in an effort to disseminate knowledge of food values in the widest possible manner. However, it has already been pointed out that emphasis on greater use of the "protective foods" cannot solve the problem of increased B₁ supply. In this connection the emphasis will have to be placed on greater use of legumes and nuts, but this line of action can be effective only within rather narrow limits because of the high energy value of these foods.

As a free people must necessarily exercise choices when securing their foods, one basic objective of all efforts directed toward improvement of our dietaries should be to see that, with the various foods readily available, it is exceedingly difficult for any one over a reasonable period, whether he knows a great deal about the science of nutrition or not, to make a set of food selections that is seriously in error. Putting the matter the other way, we should aim at making the conditions of food supply such as to yield with the greatest of ease diets that are excellent in every respect.

What lines of action are possible when attempting to deal constructively with this problem? In the educational work emphasis could be laid on greater use of the "undermilled" cereal products, under which heading shall be included whole-meal flour and other fractions, such as middlings. In view of the experience of governmental and health authorities in the Far East dealing with the problem of too great use of polished rice to the exclusion of the undermilled varieties, this

plan of attack would probably be of only limited usefulness. No doubt a certain small fraction of the population will respond to educational efforts emphasizing the high B₁ value of the undermilled cereals, and to this extent such efforts will yield satisfactory returns. The greater part of the population will still find the white highly milled flour possessing the greatest appeal, if past experience is any indication. The development of modern transportation facilities, the necessity of marketing cereals in forms that are stable for long periods and other factors peculiar to our modern complex civilization will, in my opinion, continue to give to white flour a position of prominence in our dietaries sufficiently great to mean essentially a continuance of our basic problem.

The isolation and availability through chemical synthesis of pure vitamin B₁ offers another line of attack. It is possible to add the vitamin to wheat flour in any desired and appropriate amount. Whether this is economically feasible at the present time, I leave to others to decide. No doubt also there are certain technical industrial questions involved here, but it is reasonable to believe that these are amenable to solution by research directed specifically toward that end.

In suggesting that vitamin B₁ be added to cereals, particularly wheat flour, it is pertinent to point out that flour functions essentially as a basic staple food entering into the baking of numerous special products. It is used in the manufacture not only of bread but of cakes, crackers, cookies and the like. There are, of course, many kinds of wheat flour, some suitable for making bread, others more useful for cakes, crackers, cookies and the like. For the purposes of the present discussion the word "flour" may be understood to mean all these highly milled products of the wheat berry regarded as a basic staple class of products. If this basic staple could be made a carrier of vitamin B₁, the entire pastry group of foods would no longer stand out in any dietary as essentially devoid of vitamin B₁, as is now the case. It seems reasonable to believe that through the one act of adding the vitamin to the wheat flours as a group we would increase directly the vitamin B₁ intake of a greater part of our population than could be affected by any other single step. The alternative is to encourage each of the many units of the entire baking industry to add the vitamin to its particular products. It is probably too much to expect any large measure of success in such a campaign.

How much vitamin B₁ should be added to wheat flour and other foods worthy of consideration in this connection? One cannot, of course, be dogmatic in answering this question. However, the following ideas are believed to be worthy of consideration:

Vitamin B₁ is now believed to play a role in energy metabolism, probably in the metabolic transformation of carbohydrate in the body.²⁰ It seems logical, therefore, to consider that any addition of it to a food should be made in some relation to the energy value of that food. This gives a principle applicable to a variety of foods. Another principle applicable to a refined product, wheat flour, for example, is that the vitamin be added in amounts sufficient to make its concentration approximate that present in the original unprocessed food; in the case of wheat flour this would mean adding enough vitamin B₁ to make the flour approximately equal in vitamin content to the original wheat kernel. This might be called the principle of "restoration" to be distinguished from that of "fortification," by which

is meant the addition of vitamin in such amounts as to make the concentration even greater than that of the original natural product or what the most liberal estimate of the human need for substance would indicate to be desirable.

In this connection the problem of addition of vitamin B₁ to purely artificial food mixtures designed to be more or less perfect in a nutritive sense is worthy of mention. It seems obvious that the principle of restoration can hardly apply to such situations, whereas that of securing a desirable value for the vitamin/calory or thiamin/carbohydrate-calory ratio in the final product seems peculiarly appropriate.

Elsewhere⁶ it has been pointed out that the need of adults seems to be not less than about 10 international units of the vitamin per hundred calories; children apparently require amounts ranging from 20 to 25 international units per hundred calories. The wisdom of adding the vitamin to foods in such amounts as to give at least 25 international units per hundred calories would seem to be unquestioned, because this would be bringing the product up to the irreducible minimum for a child and making it a little better than that needed by an adult. The desirability of a higher standard than this is therefore obvious. If the "restoration" of wheat flour and related grain products is taken as our guiding principle, flour would contain approximately twice the minimum for children that has been mentioned. Another point of view, valuable in this connection, relates the amount of vitamin in the "restored" product to the quantity obtained daily when customary amounts of the product are eaten. The effect of a substitution in present dietaries of "restored" flours should be essentially a "restoration" of our present dietaries to those in common use a century ago and discussed earlier in this paper. In quantitative terms this would mean that our average daily diet would contain from about 1,000 to 1,200 international units of the vitamin instead of the present 450 to 550 units.

The question might well be asked: Should wheat flour and related foods ever be given more vitamin B₁ than sufficient to "restore" them to the native cereal from which they were obtained, and if so, what limitation to such "fortification" would be reasonable? In attempting to answer this question one might draw on the scientific literature dealing with the problem of relative requirements for special situations, lactation for example, in contrast to that for mere maintenance of the adult or for normal growth of the young. Studies of lactation in the rat⁶ indicate that, in order to nurse a litter successfully to weaning, the mother rat requires from three to five times as much vitamin B₁ as she requires for her own maintenance metabolism. Mention has already been made of studies indicating that growing children show optimal retention of B₁ when receiving about 25 international units per hundred calories. This may be compared with an estimate of about 10 international units per hundred calories needed by the adult. Here the factor proves to be 2½. Evidently a factor of safety of at least 3 could be regarded as having some scientific justification. From this point of view one is led to the suggestion that the addition to a food product intended for general use of thiamin in such amount as to give 75 international units per hundred calories could be regarded as reasonable, although this concentration would in fact exceed somewhat that characteristic of the whole grains. Perhaps the simplest solution of the question would be to take the highest natural concentration in the class of whole-grain foods as the standard of maximum to apply when

the vitamin is being added to a *general purpose* food. Greater concentrations, representing true "fortifications," could then characterize *special purpose* foods, and in such cases the amount of vitamin to be added could be determined by the particular purpose aimed at in the preparation of the product, and other pertinent considerations.

This principle of securing a desirable vitamin/calory ratio is, after all, not anything really new. Students of nutrition have long related the minimal needs for other factors to the energy yielded by the diet. For example, the requirement of calcium is often stated as being not less than 23 mg. per hundred calories, that for phosphorus at least 44 mg. per hundred calories, that of iron about 0.5 mg. per hundred calories and so on.

As living organisms tend to regulate their food intake to meet their energy needs, probably because the requirement for this factor is so dominant in most situations, it is logical to relate the demands of non-energy yielding nutrients to the caloric need. What may be new in the suggestion made here is the application of this principle to individual foods instead of the dietary as a whole or the person consuming the food. Such a use of this principle appears warranted, particularly when foods are to be manipulated, so to speak, to be modified by addition of special desirable factors, and this is essentially the situation presented by the problem under consideration. The application of this principle, particularly with respect to vitamin B₁, to wheat and other grains and their products now constituting such a large part of the American dietaries would, in my opinion, be definitely in the interest of public health and welfare.

Students of the vitamins are aware that these important dietary factors are now exploited vigorously in the pharmaceutical trade. It is my opinion that the American people should, if possible, obtain their needed vitamins from foods rather than from pharmaceutical preparations. The preparations available in the local drug store should be those desired by the physician in the treatment of special cases which involve vitamin deficiencies. It is certainly not the ideal solution of our basic problem of improving the general nutrition of the American people to advocate that they make greater use of the various vitamin B₁ preparations now available essentially as pharmaceuticals, because the people most in need of the vitamin happen to be those with the least money to spend for necessities. We are thus brought around to the need for improving our important widely available and widely accepted foods. If certain basic energy-rich staples are made the appropriate carriers of the needed vitamins, as was pointed out previously, this single step affects more persons in the desired way than any other that can be devised.

SUMMARY

There are grounds for believing that American dietaries as a whole are unsatisfactory with respect to the content of vitamin B₁. The examination of available food statistics as well as of recently collected American dietaries, the observations of clinicians concerning the high therapeutic value of vitamin B₁ in conditions hitherto not suspected to be due to lack of this factor, and the observations of the value of added vitamin B₁ to the dietaries of many children all support this belief. It is believed that prosecution of a program fostering addition of vitamin B₁ to staple American foods according to the principles discussed in the present report would be definitely in the interests of the public.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - : Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, DECEMBER 9, 1939

The Platform of the American Medical Association

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.
2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.
3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.
4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.
5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.
6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.
7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.
8. Expansion of public health and medical services consistent with the American system of democracy.

SPONTANEOUS PANCREATIC HYPOGLYCEMIA

In THE JOURNAL, ten years ago, appeared a report by Howland, Campbell, Maltby and Robinson,¹ of Toronto, describing a case of dysinsulinism of six years' duration in which there were attacks of coma and convulsions. These attacks were found to be caused by low blood sugar levels and could be warded off by the administration of food. The case was diagnosed as an islet cell tumor of the pancreas; Roscoe R. Graham found and removed a tumor which the authors considered to be a slow growing carcinoma of the islands of Langerhans and from which insulin could be recovered. The patient made a complete recovery. A more recent report by Campbell, Graham and Robinson,² of the same clinic, states that the patient has now been well and free from any disability related to the uncontrolled overproduction of insulin for more than ten years.

The protean manifestations of the hypoglycemia complex have been exhaustively treated by Harris, Whipple, Wauchope and Sigwald. However, unless one becomes, as Harris puts it, "hyperinsulinism conscious," diagnostic errors may yield diagnoses ranging all the way from neurasthenia to epilepsy and brain tumor.

Banting and his associates recognized the dangers which may arise from reducing the blood sugar too far below the normal level. The most commonly observed manifestations of insulin shock are nervousness, trembling, weakness, faintness, hunger which may be agonizing, vertigo, diplopia, mental confusion resembling alcoholic intoxication, excitement, amnesia, dysarthria, sensory and motor aphasia, delirium, coma and convulsions. Harris³ in 1924 conceived of hyperinsulinism or dysinsulinism as a clinical entity and described cases of low blood sugar in which the symptoms were improved by feeding. Hyperinsulinism or hypoglycemia appeared to be the antithesis of hypo-insulinism of diabetes.

In 1927 Wilder⁴ and his associates reported a case of hypoglycemia requiring, at the time of observation, as much as 25 Gm. of dextrose an hour to prevent convulsions. Exploratory operation by William J. Mayo revealed a large nodular pancreas with metastases to the liver. In microscopic studies the cells of this cancer bore a striking resemblance to the cells of the islands of Langerhans. Alcoholic extracts made from the cancer tissue in the liver acted like insulin on injection into rabbits. This was the first conclusive evidence of hyperinsulinism due to tumor of the islands of Langerhans.

2. Campbell, W. R.; Graham, R. R., and Robinson, W. L.: Islet Cell Tumors of the Pancreas, Am. J. M. Sc. 198: 445 (Oct.) 1939.

3. Harris, Seale: The Diagnosis and Treatment of Hyperinsulinism, Ann. Int. Med. 10: 514 (Oct.) 1936.

4. Wilder, R. M.; Allan, F. N.; Power, M. H., and Robertson, H. F.: Carcinoma of the Islands of the Pancreas: Hyperinsulinism and Hypoglycemia, J. A. M. A. 89: 348 (July 30) 1927.

In the next decade the number of cases diagnosed and successfully treated or identified at necropsy increased to about 100; the largest single series were those of Whipple and of Womack and Leary. The cases fall into two groups: (1) those with morphologic changes in the islands of pancreas and (2) those without detectable alterations in the pancreas. The organic changes are of three types: (1) general hypertrophy and hyperplasia of the islands of Langerhans, (2) adenoma and (3) carcinoma. Carcinoma of the islands appears to be rare, not more than thirteen cases being reported in the literature. Islet adenomas, on the other hand, are common and deserve special mention. Frantz and Whipple⁵ compiled twenty-one cases of islet adenomas found at operation and ten at necropsy, to which Womack added fourteen. These unusually small tumors are situated most frequently in the tail and less frequently in the body or the head of the pancreas. The tumors are reddish and are clearly demarcated from the normal pancreatic tissue. They are usually single but may be multiple. Microscopically they consist of beta cells of varying degrees of maturity. While the concentration of insulin in these tumors was found to be from four to forty times that of normal pancreas, the total amount was not equal to that of normal pancreas. The hyperinsulinism or dysinsulinism is probably due to the fact that the production and release of insulin from the islet cells of the adenoma is not under the neurohormonal control which so delicately balances this process in a normal pancreas.

The diagnosis of pancreatic hypoglycemia is made from a careful consideration of the anamnesis and repeated determinations of fasting blood sugar and dextrose tolerance. Sooner or later the patients notice the association between attacks and hunger. The eating of sweet food is most effective in relieving the symptoms. In the differential diagnosis, hypoglycemia due to disturbances of the liver, the hypophysis or the adrenal glands must be eliminated. Dietetic treatment may prove successful in the milder cases and may be tried. Progression of the symptoms, however, justifies surgical intervention. The best results thus far have been obtained in cases of islet adenomas. Womack⁶ states that "clinical surgery offers few examples where the recovery is so complete or so dramatic as from the complete removal of an islet tumor." Resection of the greater portion of the pancreas in cases without pathologic changes has not been as successful. Among the notable exceptions is the remarkable case reported by Graham and Hartmann⁷ in which from 80 to 90 per cent of the pancreas was removed from a baby 1 year of age for chronic hypoglycemia with repeated convulsions and marked retardation in mental development. All the symptoms promptly disappeared and

have not recurred. The mental and physical states of the patient have shown marked improvement since the operation. The pancreatic tissue removed was essentially normal.

INDUSTRIAL UTILIZATION OF DAIRY PRODUCTS

Of the hundred billion pounds of milk produced annually in the United States, 46 per cent is separated to obtain cream. The skim milk which results from this operation contains vast amounts of substances which are of industrial importance and for which new uses are being sought. Skim milk, for instance, is rich in casein and lactose. Similarly, a high percentage of lactose is present in the whey obtained in the manufacture of cheese. Particularly during the last few years a considerable amount of attention has been centered on the industrial utilization of some of the by-products of the dairy industry, and a number of the achievements which have been made in this direction were discussed at a recent symposium.¹

Casein has long been used in the manufacture of various types of adhesives and may also be used to prepare plastic materials such as artificial horn or artificial ivory. A few years ago a process was discovered for converting casein into textile fiber and this new use is now attracting attention in several countries. At present Italian, Netherland and British firms are reported to be engaged in producing casein fiber, and a patent for its production has already been granted in the United States. The European production of casein fiber in 1938 was probably between six and eight million pounds. The high cost of silk induced the development of rayon and, in the same sense, the comparatively high cost of wool has given impetus to a search for cheaper substitutes. In this country there is reportedly a potential annual supply of skim milk of forty billion pounds over and above that now converted into industrial products and, according to investigators in the United States Department of Agriculture,¹ it should be possible for casein fiber to be produced much more cheaply than wool. Whether or not casein fiber will be used extensively in this country as a diluent or extender of wool remains to be seen. Stable knitted rayon is being used for this purpose at present, but casein fiber has the important advantages that it can be dyed with wool dyes and can be laundered by the same methods as wool.

Whey is obtained in large quantities as a by-product both in the manufacture of cheese from whole milk and in the manufacture of casein from skim milk. As improved transportation facilities permit the bringing of more milk to centrally located factories, not only is the farmer deprived of a valuable feed but the disposal

1. Whittier, E. O., and Gould, S. P.: *Indust. & Engin. Chem., News Edition* **17**: 369, 1939. Smith, L. T., and Claborn, H. V., *ibid.* **17**: 370, 1939. Papers presented as part of the Joint Symposium on the Industrial Utilization of Dairy Products before the Divisions of Agricultural and Food Chemistry and Biological Chemistry at the ninety-seventh meeting of the American Chemical Society, Baltimore, April 4, 1939.

of whey becomes a problem. Cheese factories converted more than a million pounds of whey into powder in 1937, and investigators in the United States Department of Agriculture have already devised a process for separating the whey powder into lactose, a protein-rich concentrate, and a solution rich in vitamin G. The lactose may be used in medicinal preparations and in infant foods as well as in the manufacture of candy. The production of lactic acid by fermentation of the lactose in whey is also a commercial activity at the present time, and the lactic acid thus produced has a wide variety of uses as an acidulant in food products such as fruit essences, extracts, syrups and baking powder. It has even been used recently in effervescent beverages in the place of citric acid. Certain esters of lactic acid may also be converted by suitable treatment into methyl acrylate, for which there is a wide variety of possible uses in the manufacture of plastic materials. It seems probable that in the near future lactic acid will play an increasingly important part in the field of solvents, in plastics, and as an acidulant for beverages and foods.

Important advances have been made in the direction of the utilization of by-products of the dairy industry. These developments are of particular interest as they involve the important nutrient milk. Moreover, some of the by-products may, in turn, be incorporated in certain foods as well as used in the manufacture of pharmaceuticals.

Current Comment

HISTAMINE IN PLATELETS OF RABBITS

From experiments originally intended to demonstrate the changes in blood histamine following vaccine administration, Zon, Ceder and Crigler¹ obtained evidence suggesting that it is the platelets which carry major portions of the blood histamine. The rabbits in the experiment were sensitized to a strain of beta-hemolytic streptococcus of low virulence. Following the intravenous administration of 10 cc. of the killed homologous vaccine to sensitized animals and also to nonsensitized controls, blood samples were withdrawn and platelets, white cells and histamine were determined. There was an almost complete disappearance of granulocytic cells following the vaccine with little change in the total histamine content. Further, there was no increase in plasma histamine, which ruled out any shift in histamine from injured white cells to plasma. It was also shown that the administration of antiplatelet serum caused a significant drop in blood histamine generally paralleling the drop in platelets. Likewise fractional centrifugation of platelet containing plasma removed histamine almost in the same proportion as the platelets. This demonstration of the distribution of histamine should be of importance in future investigations on this interesting blood constituent.

"TIME" MARCHES ON!

In the issue of *Time* for December 4 appeared an article entitled "Misery Harbor," purporting to describe the recent changes in the administration of the Cook County Hospital in Chicago. The title "Misery Harbor" is taken from a series of articles which appeared in the *Chicago Daily Times* following an investigation of the hospital made by that newspaper more than a year ago. The article in *Time* is mentioned here because it is replete with absolute misstatements of fact beyond anything of a similar character published in the field of medicine even in that periodical during recent years. Indeed the article betrays a carelessness almost incomprehensible in a periodical which has in the past frequently gone to extended lengths to secure accuracy.

Briefly there follows a list of statements made by *Time* and thereafter the correct statement:

1. "During the last four years Cook County Hospital has been a battleground for two warring medical factions." There has been no battle between two warring medical factions.
2. "Last week a compromise ended the fight." There has been no compromise.
3. "Dr. Meyer never required the hospital's army of interns to attend postgraduate classes or lectures." Lectures and conferences for interns have been held for at least ten years.
4. "The American Medical Association . . . believes that all interns should taper off into actual practice with at least eighty hours of medical lectures during internship." No specific number of hours of instruction has ever been mentioned, much less required, by the Council on Medical Education and Hospitals.
5. "Consequently, four years ago, the A. M. A. dropped Cook County Hospital from its list of approved hospitals . . ." Obviously the number of lecture hours was in no wise involved.
6. "Over this point Cook County's Dr. Meyer and A. M. A.'s education secretary, Dr. Irving Samuel Cutter . . ." Dr. Irving S. Cutter is not the A. M. A.'s education secretary; he is Dean of Northwestern University School of Medicine.
7. ". . . thus automatically cutting off Dr. Meyer's supply of interns from topflight medical schools." At no time has the County Hospital failed to obtain interns from the four recognized medical schools of Chicago. No others are eligible for appointment.
8. ". . . A. M. A. last spring brought public opinion to bear." At no time has the A. M. A. made any attempt to influence public opinion concerning the County Hospital. It has studiously refrained from comment upon the situation.
9. "An A. M. A.-inspired citizens' committee . . ." The A. M. A. had nothing whatever to do with the "Citizens' Committee" which was appointed by the Board of County Commissioners upon the recommendation of a committee of hospital experts previously employed by the County Board to investigate and report upon conditions at the County Hospital.
10. Said committee ". . . hinted that the hospital might be reinstated on the A. M. A.'s list if a new director acceptable to the A. M. A. were chosen." As stated above, the Citizens' Committee had no connection whatever with the A. M. A. and therefore could not and did not claim to represent it.
11. "(2) Cook County was promised reinstatement on the A. M. A.'s list some time around Jan. 1; . . ." No such promise was given.

Immediately on the appearance of this article a telegram was sent to *Time* calling attention to some of these inaccuracies. The inaccuracies are all the more unfortunate because it would have been exceedingly simple merely by the use of the telephone, since *Time* is printed in Chicago, to secure the facts. It will be interesting to see how far *Time* goes in its correction.

ORGANIZATION SECTION

THE SIXTEENTH DECENNIAL CENSUS IN 1940

PREPARED ESPECIALLY FOR THE JOURNAL BY THE BUREAU OF THE CENSUS

There is one division of the Bureau of the Census with which every doctor in America who has ever lost a patient or attended at the birth of a new one has had contact, whether he knows it or not, and that is the Division of Vital Statistics. Eventually, through one means or another—state bureaus of public health, usually—every birth and death certificate issued in America reaches the office of the division, where, along with the millions of others of its kind, it is added to the records from which our national birth and death rates are computed, the incidence of death from certain major diseases, which the division calls "The Killers," is ascertained, the frequency of death by accident, and what type of accident, is figured and a dozen or so other enormously valuable sets of vital statistics are acquired, on the basis of which state boards, county organizations, hospitals, medical associations and individual doctors themselves can plan medical campaigns, campaigns for public health and safety, and budgets for sanitary and institutional improvements.

But the great ten year census of population, the sixteenth such, to begin April 1, 1940, will add a large amount of invaluable data to the files of the medical profession. And along with it, the biennial census of manufactures and a similar one of business, both of which begin January 2 of the coming year, include statistics of a different type which are also of real value to the doctor.

Perhaps the most interesting one of the specific questions being asked in the census schedules next year is that which is being put to the druggists of this country on the questionnaire of the business census. Druggists and pharmacists are being asked what the dollar volume of their sales was in the form of doctors' prescriptions. That figure, alongside the one giving the total sales of "drugs, medicines, chemicals, compounds," will give the physician an accurate picture of the comparative amount of money being spent for proprietaries and for prescriptive medicines. These data will be broken down into state figures and when possible into figures for large cities. A further question to be asked, of some interest to the medical profession, is on the number of registered pharmacists employed. The need for skilled chemists in the average drug store is known to all physicians, and figures on the pharmacists' profession may have a tendency to increase the quality and quantity of trained personnel in this field.

The Census of Business will tabulate all drug stores by states, counties and cities and towns of 2,500 population or more. They will be listed in two main groups—those with soda fountains and those without. Each will be asked to report on the sales of various kinds of commodities sold and to give inventory totals for the beginning and close of 1939.

The Census of Manufactures, which will be taken concurrently with the business census, will present important national, state and city totals on the production of drug grinding, drugs and pharmaceuticals, biologicals and proprietary medicines. Data on this type of manufacture will be presented only by states, but

important totals on the production of major specific commodities in the drug industry will be presented in such a fashion that the medical profession will be able to draw material conclusions on trends in medication in this country. Included here also will be a breakdown between prescriptive and proprietary drugs and medicines.

The Census of Manufactures will also present valuable tables on the production of surgical appliances, rubber goods and other accessories of the doctor and will thus give something of an index of the state of health of the medical and surgical professions as a whole, and changes and trends in the use of various standard appliances and materials.

But the most important of all the censuses to be taken in 1940, for the country as a whole as well as for the physician, will be the sixteenth Decennial Census of Population. This will be the one hundred and fiftieth anniversary of the first population census in America, and, partially in celebration of the event, an effort has been made to have the census schedules more comprehensive, more scientific and more generally useful to every type of person or profession interested in people than ever before. The census itself is a task large enough to stagger the imagination. More than 130,000 enumerators will be employed for a period averaging one month—the month of April—and will be trained in the technics of census taking by 560 district supervisors. To synchronize and supervise operations as a whole, 105 area supervisors will be located in as many key cities to serve as courts of appeal and general managers of the whole enormous project.

Vitally important will be the social, economic and scientific results of the tabulations of specific answers to the various questions on the population census schedules; and it is here that the interests of the medical profession are closely involved. There are two major ways in which the population census is of importance to all physicians:

The first concerns the profession itself. The 1940 census will show, with a high degree of accuracy, exactly what the distribution of doctors is throughout the country. The figures will be presented by states, by cities of 100,000 and over and by cities of from 25,000 to 100,000 and will give the exact numbers of physicians and surgeons, osteopaths, nurses, veterinary surgeons and dentists, as well as such "semiprofessional" classifications as chiropractors, "healers, not elsewhere classified," technicians and laboratory assistants, and physicians', surgeons' and dentists' assistants. By a careful study of these data individual practitioners, state and county medical associations, hospitals and state and municipal public health groups can arrive at sound conclusions concerning the number of doctors in particular areas and the need for more such professional men, if any. The serious problem of the unequal distribution of medical men throughout the country can thus be scientifically approached by means of the census data.

Figures of this sort can obviously be of enormous value not only to the groups that have been named but

to the country's legislative bodies in their attempt to establish higher types of requirements for medical practice and to supply their areas with more ample institutional quarters.

The other part of the population census of especial interest to the medical profession is the general data on distribution of population itself, with especial emphasis on sex and age differentiations. These compilations draw into the picture problems of a broader social interest than those dealing specifically with the profession. The 1940 census will present accurate figures, for instance, on the extent of the decline in the birth rate in the United States and the consequent increase in the number of aged persons. Resulting from this may be many changes of decision on the part of young students in medical schools who might have decided to take up obstetrics or allied branches of medicine or surgery but who will feel that the decline in the birth rate may have catastrophic results on their practice as the trend increases and the number of babies born drops. Hospitals and sanatoriums may find such figures of value in case they plan any expansion, for, as the birth rate declines, the rate and number of aged persons increases, and the need for old age homes and for hospitals devoted to the care of diseases of the aged increases over and above the need for lying-in hospitals.

This whole problem of a declining birth rate is, of course, one of national importance, which has reverberations far beyond the medical profession alone. Similarly the question of the trends in population shift are countrywide in significance, in addition to having a very definite bearing on the question of distribution of medical services. There seems recently to have come a stop to the tendency of people to move to the cities from the farm, but it is impossible to tell, without the data from the 1940 census, how large or how significant this change of trend is.

There are naturally many specific problems in the medical profession on which the census cannot touch, such as professional standards and scientific advances

in surgical technics and the materia medica. Material of this sort is the specific province of the American Medical Association, and its data are more complete, more accurate and more up to date than any similar figures could be when taken on a broad population basis. But it remains that the largest problems confronting the profession are those which are dealt with by the Bureau of the Census in its forthcoming decennial census and in the Division of Vital Statistics in its frequent releases on causes of death, hospital statistics, birth registration and so on.

Certainly if there is one government department of supreme value to physicians as a whole, it is the Bureau of the Census. If all members of the profession will remember this when the census enumerators call on them sometime in April and cooperate to the best of their ability in the filling out of the schedules promptly and accurately, they can be assured that the resultant data will be just that much more valuable to them, once they are compiled and published. And if any of the questions seem to the individual physician to be somewhat personal and private in nature, he should remember that all information collected by the enumerators is held strictly confidential by them and by the statisticians and population scientists in Washington; that they are under oath never to reveal any of the information which goes through their hands either to individuals or to any society, association or government department whatsoever; and that Congress has made the answering of these questions obligatory on the individual, in an effort to assure the country as a whole of accurate, complete and therefore socially valuable statistics concerning the people of America.

With the cooperation of the medical profession freely and willingly granted to the census enumerators, doctors can be assured that the results of the 1940 decennial census will be of such a nature as to aid them greatly in their personal affairs, their local and state problems, and the national problems of health as a whole.

WOMAN'S AUXILIARY

Colorado

The annual meeting of the auxiliary to the Colorado State Medical Society was held in Colorado Springs October 5-7. Dr. H. E. Harms was speaker at the luncheon meeting, which was attended by 120 auxiliary members and guests. More than eighty members attended the first autumn meeting of the auxiliary to the Denver County Medical Society, which was held at the Denver General Hospital October 18.

Florida

The Palm Beach Medical Society and the auxiliary entertained doctors and their wives who attended the third annual meeting of the Southeast District Medical Society in West Palm Beach October 12. An auxiliary to the district medical society was organized, and Mrs. H. A. Leavitt, Miami, was elected president. Speakers at the meeting were Mrs. L. C. Ingram, president of the auxiliary to the Florida Medical Association; Mrs. Leigh Robinson, chairman of the *Hygeia* committee, and Mrs. J. W. McMurray, chairman of the exhibit committee.

Illinois

Mrs. Charles C. Winning, president of the auxiliary to the Illinois State Medical Society, spoke on auxiliary activities at a meeting of the auxiliary to the Vermilion County Medical Society in Danville October 3 and at a meeting of the auxiliary to the Logan County Medical Society in Lincoln October 26.

Group hospital insurance was discussed by Enoch J. Brand at a joint meeting of the Adams County Medical Society and its auxiliary in Quincy October 9. The auxiliary to the Knox County Medical Society met at the Galesburg Club, Galesburg, October 20. Articles from *THE JOURNAL* on the national health program were read, and plans were made for distributing *Hygeia* in the county.

The auxiliary to the Will-Grundy County Medical Society met in Joliet October 10. Reports were given on articles published in *Hygeia* and the *Illinois Health Messenger*. Members were asked to study editorials and sections devoted to medical economics in *THE JOURNAL* and the *Illinois Medical Journal*.

Mrs. W. J. Wanninger, chairman of the *Hygeia* committee of the auxiliary to the Illinois State Medical Society, addressed a group meeting of the auxiliary to the Chicago Medical Society at the home of Mrs. William D. Cutter October 16. Mrs. Wanninger emphasized the importance of placing *Hygeia* in the schools and reading rooms of every community in Illinois. Dr. Charles Papik discussed "An Old Age Plan for Doctors and Their Wives" at a group meeting of the auxiliary to the Chicago Medical Society at the Englewood Hospital.

Members of the Irving Park group of the auxiliary to the Chicago Medical Society met at the Municipal Tubercular Sanitarium, September 26. Addresses were given by Drs. Henry C. Sweeney, Richard M. Davison and Meyer Lichtenstein, members of the staff of the Sanitarium.

ORGANIZATION SECTION

2157

Iowa
The board of directors of the auxiliary to the Iowa State Medical Society met in Des Moines September 22; Mrs. Edward A. Hanske, Bellevue, is president. Mental hygiene is the topic of study for the year. The Speakers' Bureau, the Hygeia clipping bureau and copies of radio broadcasts on health will be sent by the Committee on Public Relations for its work during the year.

Louisiana
The auxiliary to the Caddo Parish Medical Society met in Shreveport October 11. Mrs. S. M. Blackshear, president of the auxiliary to the Louisiana State Medical Society, spoke on the aims and accomplishments of the state auxiliary. Mrs. Blackshear was speaker also at the first quarterly meeting of the auxiliary to the Lafayette Parish Medical Society in Lafayette October 19. Mr. Gung-Hsing Wang, Chinese vice consul, spoke on "The International Situation Through the Chinese Window" before the auxiliary to the Orleans Parish Medical Society in New Orleans October 11. A committee was formed to do extra work for the Red Cross and to assist in raising funds for the Community Chest.

Dr. John Pracher, president, Ouachita Parish Medical Society, addressed the members of the parish auxiliary at a meeting in

Tennessee
Monroe October 12 on the subject "Blood Transfusion." The auxiliary to the Second District Medical Society met in Norco October 17; Mrs. S. M. Blackshear addressed the members. The wife of every member of the St. Tammany Parish Medical Society is a member of the auxiliary.

The board of directors of the auxiliary to the Tennessee State Medical Association met in Nashville September 29. Following the business session and luncheon, Mrs. Matt B. Murfree, of Murfreesboro, president of the auxiliary, read "The Eulogy of the Doctor," written by Robert Louis Stevenson. The annual social meeting of the Knox County Medical Society and its auxiliary was held September 16 at the home of Dr. and Mrs. J. B. Neil. About 100 physicians and their wives were in attendance.

Wisconsin
More than 125 members and guests attended a meeting of the auxiliary to the Milwaukee County Medical Society in Milwaukee October 13. Prof. Harold Ehrensperger of Northwestern University, Evanston, Ill., spoke on "Drama and Propaganda."

OFFICIAL NOTES

THE NEW YORK SESSION

Section Representatives to the Scientific Exhibit
The various sections of the Scientific Assembly have appointed representatives to the Scientific Exhibit to assist and advise in the procurement and selection of exhibits for the New York session, June 10-14, 1940. The following appointments have been made:

Practice of Medicine—Fred M. Smith, Iowa City.
Surgery, General and Abdominal—Grover C. Penberthy, Detroit.
Obstetrics and Gynecology—H. Close Hesselstine, Chicago.
Ophthalmology—Georgiana Dvorak Theobald, Oak Park, Ill.
Laryngology—Arthur F. Abt, Chicago.
Pediatrics—Daniel S. Cunningham, New York.
Pharmacology and Therapeutics—Wallace M. Yater, Washington, D. C.
Pathology and Physiology—F. W. Konzelmann, Philadelphia.
Nervous and Mental Diseases—F. P. Moersch, Rochester, Minn.
Dermatology and Syphilology—Hamilton Montgomery, Rochester, Minn.
Preventive and Industrial Medicine and Public Health—Paul A. Davis, Akron, Ohio.
Urology—John H. Morrissey, New York.
Orthopedic Surgery—Mather Cleveland, New York.
Gastro-Enterology and Proctology—Sara M. Jordan, Boston.
Radiology—S. W. Donaldson, Ann Arbor, Mich.

Application blanks for space in the Scientific Exhibit may be obtained from the section representatives or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago, Ill.

RADIO BROADCASTS

The seventh season of broadcasting by the American Medical Association over the facilities of the National Broadcasting Company and affiliated stations is now under way with programs scheduled each Thursday at 4:30 p. m. eastern standard time (3:30 central standard time, 2:30 mountain time and 1:30 Pacific time). The program is on the Blue network of the National Broadcasting Company, the key station of which is WJZ, New York.

It is impossible to publish a list of topics in advance when programs are developed from last minute proof pages of THE JOURNAL. It is possible to say that future programs under consideration involve one each dealing with progress in medicine, rabies, infantile paralysis, maternal and child health, hospitals, medical education and industrial health. These programs will be as appropriate as possible to the season at which greatest interest in these topics is manifested. The programs on hospitals, medical education and industrial health will correspond with publication dates of special numbers of THE JOURNAL devoted to these topics. The program on medical progress will be broadcast December 28. The programs on maternal and child health will be a part of the spring series.

A special program in cooperation with the National Foundation for Infantile Paralysis, Inc., and the Committee for the Celebration of the President's Birthday is scheduled to appear as the regular program dated January 11. Lists of radio stations which have signified their intention of broadcasting Medicine in the News, according to information received from the National Broadcasting Company, were published in THE JOURNAL, December 2, page 2065.

EDUCATION AND LICENSURE

The thirty-sixth Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, Feb. 12 and 13, 1940. The Federation of State Medical Boards of the United States will participate in the congress. Topics and speakers are as follows:

Report of the Council on Medical Education and Hospitals.
Ray Lynnan Wilbur, M.D., LL.D., Chairman, Stanford University, Calif.
(Subject to Be Announced.)
Alan Gregg, M.D., Director, The Medical Sciences, Rockefeller Foundation, New York.
Professional Education.
C. S. Boucher, Ph.D., Chancellor, University of Nebraska, Lincoln.
The Goal of Medical Education.
Irvin Abell, M.D., Vice Chairman, Board of Regents, American College of Surgeons, Louisville, Ky.
Graduate Work in Medical Areas.
George D. Stoddard, Ph.D., Dean, Graduate College, State University of Iowa, Iowa City.
Trends in Liberal Arts Education.
George A. Works, Ed.D., Professor of Higher Education, Department of Education, University of Chicago.
The Place of Malignant Disease in the Medical Curriculum.
Ludvig Hektoen, M.D., LL.D., Executive Director, National Advisory Cancer Council, Washington, D. C.
Medical Education—1905 to 1940.
Morris Fishbein, M.D., Editor, JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Chicago.
(Subject to Be Announced.)
Irving S. Cutter, M.D., LL.D., Dean, Northwestern University Medical School, Chicago.
The Work of the National Board of Medical Examiners During Its First Quarter Century.
Louis B. Wilson, M.D., Director Emeritus, Mayo Foundation for Medical Education and Research, Rochester, Minn.
Program for the Instruction of Interns.
Nathan B. Van Eetten, M.D., President-Elect, American Medical Association, New York; Nathan Davis, M.D., New York.
The Recognition of Professional Aims in the Teaching of the Fundamental Medical Sciences.
M. B. Visscher, M.D., Ph.D., Professor of Physiology, University of Minnesota Medical School, Minneapolis.
Role That a Children's Hospital Should Play in the Community.
Alan Brown, M.D., Professor of Pediatrics, University of Toronto Faculty of Medicine, Ontario.
Licensing the Professions.
Miss Frances P. De Lancy, Department of Political Science, West Virginia University, Morgantown.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meetings.—At a meeting of the Third Councilor District Medical Society in Stuttgart October 26 the speakers included Drs. Clyde D. Rodgers, Little Rock, on "Puerperal Disorders in Obstetrics"; Silas C. Fulmer, Little Rock, "Hypertension"; William C. Chaney, Memphis, Tenn., "The Medical Man and His Neurologic Problems," and Henry T. Smith, McGehee, "The Future of Organized Medicine."—The Second Councilor District Medical Society was addressed in Searcy October 19 by Drs. Rufus B. Robins and Samuel A. Thompson, both of Camden, on "Some Remarks on Head Injuries" and "Heart Problems in the Smaller Centers" respectively. Dr. Albert S. Buchanan, Prescott, president of the state medical society, also spoke.—The First Councilor District Medical Society was addressed at Paragould October 17 among others by Drs. Ralph M. Sloan, Jonesboro, on "Premature Separation of the Placenta"; Charles S. Paddock, Memphis, Tenn., "Pyelitis of Pregnancy," and Neuton S. Stern, Memphis, "Acute Angina."

CALIFORNIA

Personal.—Dr. Ruggles A. Cushman has retired as superintendent of the Mendocino State Hospital, Talmage; he served as assistant superintendent of the hospital from 1904 to 1910 and had been superintendent since 1932.

Society News.—At a meeting of the Riverside County Medical Association in Riverside recently Dr. William E. Gardner discussed "Obstructions in Urology."—Among others, Dr. Paul A. Gliebe, San Francisco, spoke on "Psychiatry and the General Practitioner" before the San Joaquin County Medical Society in Stockton recently.—Dr. Emile F. Holman, San Francisco, addressed the San Diego County Medical Society November 14 on "Arteriovenous Aneurysm, Experimental and Clinical Considerations."—Dr. Anton S. Yuskis discussed "Embolie Manifestations of Heart Disease" before the San Diego Galen Club October 24.—At a meeting of the Los Angeles Surgical Society November 10 the speakers were Drs. Ralph T. Richards, Salt Lake City, on "Use of Oxygen and Carbon Dioxide in Surgery"; Verne C. Hunt, "Total Gastrectomy," and Lowell S. Goin, "Observations on Refrigeration Therapy for Malignant Disease."

GEORGIA

Special Society Election.—Dr. Robert L. Rhodes, Augusta, was recently elected president of the Georgia Industrial Surgeons' Association. Other officers are Drs. Richard E. Newberry, Atlanta, vice president, and John W. Simmons, Brunswick, secretary.

Personal.—Dr. Robert C. Pendergrass has been appointed director of a newly organized cancer clinic in Americus.—Dr. Jack R. McMichael, Quitman, has been appointed a member of the state board of health.—Dr. Clarence L. Ayers, Toccoa, has been appointed a member of the state board of health for a six year term.

Annual Pediatric Meeting.—The Georgia Pediatric Society will hold its annual scientific session in Atlanta December 16. The speakers will include Drs. George M. Lyon, Huntington, W. Va., on "Meningococcic Meningitis and Its Management" and "Purulent Meningitis Due to Other Than the Meningococcus"; Harry Bakwin, New York (subjects not announced), and Charles F. McKhann, Boston, "Poliomyelitis" and "Progress in the Control of Respiratory Infections." Dr. Lewellyn H. Muse, Atlanta, is president of the society and Dr. Don F. Cathcart, Atlanta, secretary-treasurer.

ILLINOIS

Society News.—Dr. Oliver E. Van Alyea, Chicago, discussed "Irrigation of the Frontal and Maxillary Sinuses" before the Rock River Valley Eye, Ear, Nose and Throat Society in Rockford November 21.—Dr. Frederick A. Jostes, St. Louis, discussed "Backache: A Manipulative Treatment Without Anesthesia" at a meeting of the Adams County Medical Society in Quincy November 13.

Chicago

New Position at Cook County Hospital.—Dr. Marshall Davison, chairman of the surgical division of Cook County Hospital, has been appointed medical director of the hospital, a newly created position. In this capacity Dr. Davison will coordinate and correlate activities of the staff and have jurisdiction over all medical and surgical work at the hospital. Dr. Karl Meyer will continue as medical superintendent. Dr. Davison graduated at the University of Illinois College of Medicine in 1920. He is assistant professor of surgery at Northwestern University Medical School.

INDIANA

Changes in Health Officers.—Dr. Wendell C. Anderson, Mentone, has been appointed director of the district health department, covering Dubois, Spencer, Orange, Crawford and Perry counties, with headquarters in Huntingburg. He succeeds Dr. Chester A. Hicks. Dr. Lewis C. Robbins, formerly of Baltimore, has been placed in charge of the district health unit covering Monroe, Brown and Lawrence counties, with headquarters in Bloomington. He succeeds Dr. Henry G. Steinmetz, who has received a fellowship in public health at Johns Hopkins University.

District Meetings.—At a meeting of the Thirteenth District Medical Society November 8, Laporte, Drs. Fred W. Bailey, St. Louis, among others, discussed diagnosis and treatment of nonpenetrating intra-abdominal injuries, and Edwin M. Miller, Chicago, treatment of severe fractures of the elbow in children.—The Seventh District Medical Society was addressed in Martinsville November 15 by Drs. Carl P. Huber, Indianapolis, on "Toxemias of Pregnancy"; Maurice L. Blatt, Chicago, "Care of the Premature and Newborn Infant"; Robert M. Moore, Indianapolis, "Some Helpful Clinical Observations in Angina Pectoris"; Karl R. Ruddell, Indianapolis, "Acute Appendicitis." Dr. M. Herbert Barker, Chicago, addressed the dinner session on "Management of Pneumonia in Children and Adults."

KANSAS

Lectures on Medical History.—The Kansas University School of Medicine, in commemoration of the opening of its new library and museum of medical history, is presenting a series of lectures on medical history. Dr. Sanford V. Larkey, librarian of the William H. Welch Memorial Library, Johns Hopkins University School of Medicine, Baltimore, gave the first lectures October 9 on "Primitive Medicine" and "Egyptian Medicine." Other lecturers include:

Dr. John Farquhar Fulton, New Haven, Conn., January 15, History of Physiology.
Dr. Henry E. Sigerist, Baltimore, March 4, Methods of Medical History and the Future of Medicine in the Light of History.
Chauncey D. Leake, Ph.D., San Francisco, March 11 (date tentative), History and the Development of Therapeutic Drugs and the History of Anesthesia.

MARYLAND

University News.—Dr. Charles Edward Smith, associate professor of public health and preventive medicine, Stanford University School of Medicine, San Francisco, delivered a public lecture at the Johns Hopkins School of Hygiene and Public Health, Baltimore, November 7, on "Epidemiology of Acute Coccidioidomycosis with Erythema Nodosum ('San Joaquin' or 'Valley Fever')." This was one in the series of the De Lamar Lectures in Hygiene.

Society News.—A symposium on Rocky Mountain spotted fever was presented before the Baltimore City Medical Society November 3 by Drs. Thomas Nelson Carey, Charles H. Halliday and Rolla E. Dyer, U. S. Public Health Service. At a day and night meeting November 17 Drs. Warfield M. Firor and George W. Thorn discussed "The Modern Treatment of Addison's Disease" and Dr. Edward S. Stafford, "Mortality from Appendicitis."—Dr. William S. Love Jr., Baltimore, discussed symptomatology, diagnosis and treatment of coronary thrombosis before the Harford County Medical Society in Bel Air recently.

Study of Hearing of School Children.—A study of selected school children to detect impaired hearing will be carried out in the Eastern Health District, according to Baltimore *Health News*. The work will be done under the supervision of Dr. Samuel J. Crowe, adjunct professor of laryngology and otology, Johns Hopkins University School of Medicine, Baltimore, and his staff in collaboration with the departments of education and health and the Eastern Health District. The study will involve careful examination, including

an audiometric test, of 1,000 or more school children between the ages of 8 and 12. When found necessary, arrangements for adequate treatment will be made after consulting and receiving approval from the children's parents and family physicians.

MASSACHUSETTS

Conference on Physical Medicine.—The New England Society of Physical Medicine held a clinical conference November 8-10 at Boston and the Massachusetts Institute of Technology, Cambridge, November 10. Among the speakers were:

Dr. Harold E. Himwich, Albany, N. Y., Nitrogen Therapy, Physiologic Aspects in Schizophrenia.
Drs. Charles W. McClure and Isaac R. Jankelson, Boston, Gastroscopy.
Dr. Temple S. Fay, Philadelphia, Observations on Human Refrigeration.
Drs. Curtis T. Prout, Arlington Heights, Mass., and John G. Gibson II, Boston, Fever Therapy.

There were symposiums on galvanism and the sinusoidal currents, high frequency currents, phototherapy and massage and corrective exercise. At the banquet, Harold E. Edgerton, Ph.D., discussed "Seeing the Unseen with Stroboscopic Photography" and George R. Harrison, Ph.D., "Modern Physics and the Modern Physician." Dr. Henry A. Tadgell, Wrentham, is president of the society and Dr. William D. McFee, Boston, secretary.

MISSISSIPPI

Society News.—The Northeast Mississippi Thirteen Counties Medical Society was addressed recently, among others, by Drs. James A. Watt, Aberdeen, on "Migraine, Its Present Day Concept and Treatment"; Claud F. Gilbert, Corinth, "Pre-natal Care"; Luther L. McDougal Jr., Paris, Texas, "Feeding a Normal Infant," and Cecil D. Gaston, Birmingham, Ala., "Hemorrhoidectomy, Essentials in the Prevention of Postoperative Pain."

Health Department Activities.—Full time health departments will soon be established in Marion, Lowndes, Tate, Noxubee and Newton counties to bring the total of full time health units in the state to forty-four, newspapers announce. Dr. Robert H. Bostwick Jr., Indianola, has been made director of the Union County health department succeeding Dr. Edwin M. Butler, Liberty, who plans to enter private practice. Dr. James P. Ward, Charleston, director of Tallahatchie County, has been appointed director of the Washington County health department, effective October 15, succeeding Dr. Benjamin F. Hand Jr., who resigned to engage in private practice in Greenville, it is reported. Dr. Everett W. Ryan, Canton, formerly director of the Madison County health unit, is being transferred to Charleston to direct the Tallahatchie department.

MISSOURI

Personal.—Dr. Henry H. Sweets Jr., Louisville, Ky., has been appointed to the staff of the University of Missouri School of Medicine, succeeding Dr. James H. Peers, who recently resigned as assistant professor of pathology. Dr. Charles Wesley Burrill, Kansas City, said to be the oldest living member of the Jackson County Medical Society, was honored by friends October 21 in observance of his ninety-fourth birthday.

Society News.—At a meeting of the St. Louis County Medical Society November 22 the speakers were Drs. Peter Heinbecker on "The Surgical Treatment of Hypertension"; Nathan A. Womack, "Recent Advances in the Knowledge of Cancer," and Robert Elman, "Surgical Treatment of High Intestinal Obstruction in Infants."—Dr. William S. McCann, Rochester, N. Y., will address the Kansas City Academy of Medicine December 15 on "Modern Trends in the Study of Kidney Disease." Dr. Harold E. Himwich, Albany, N. Y., discussed "Brain Metabolism" before the academy November 17.—Dr. Oscar V. Batson, Philadelphia, addressed the Kansas City Society of Ophthalmology and Otolaryngology December 7-8 during its postgraduate session on anatomy.

Neuropsychiatrist Honored.—A meeting of the St. Louis Medical Society October 24 was held in honor of Dr. William W. Graves, professor and director of the department of neuropsychiatry, St. Louis University School of Medicine, St. Louis. At this time he was presented with a certificate of merit and a gold medal. The award of merit points out that Dr. Graves' work "resulted in new approaches to the qualitative evaluation of inherited variations in relation to the inherited predisposition of human constitution, expressed in inherited predisposition to health or disease, and in inherited capacity for education, for adaptability, and for longevity." The society has conferred this

honor on only two previous occasions: In 1927 to Dr. Evarts A. Graham and his associates, Drs. Glover H. Copher, St. Louis, Warren H. Cole, now of Chicago, and Sherwood Moore, St. Louis, for their work in cholecystography, and in 1935 to Edward A. Doisy, Ph.D., for his achievements in hormone chemistry and physiology.

NEVADA

Changes in State Board.—New members of the Nevada State Board of Medical Examiners are Drs. Frederick M. Anderson, Carson City; John Vernon Cantlon, Reno, and George R. Magee, Yerington. Drs. Robert P. Roantrce, Elko, and Ralph A. Bowdle, East Ely, continue as members. Dr. Roantrce is president and Dr. Anderson is secretary.

NEW YORK

Personal.—Dr. John Maxwell Chamberlain, formerly of Ann Arbor, Mich., has been appointed principal thoracic surgeon on the staff of the division of tuberculosis in the state department of health, Albany.—Dr. James Bernard Lawler, Vernon, has been appointed health officer of the township, except the city of Sherrill, succeeding Dr. Gary M. Lewis, who had served for sixty years except for a short period.

Society News.—Mr. J. George Crownhart, executive secretary, State Medical Society of Wisconsin, Madison, addressed the Medical Society of the County of Westchester at White Plains at its annual meeting November 21 on "Sickness Insurance in Europe."—Dr. Carl Eggers, New York, addressed the Medical Society of the County of Albany November 15 on "Carcinoma of the Breast."—Dr. John S. Lawrence, Rochester, addressed the Rochester Pathological Society November 14 on "Toxic Effects on the Blood of Sulfanilamide and Allied Drugs."—Dr. Walter C. Alvarez, Rochester, Minn., addressed the Rochester Academy of Medicine November 1 on "The Patient Who Remains Sickly in Spite of Long and Strenuous Treatment."—Dr. Jesse G. M. Bullowa, New York, addressed the Dutchess County Medical Society, Poughkeepsie, November 8 on "The Appropriate Treatment for the Pneumonias—Individualizing the Case."—Drs. John E. Free and Jay E. Meeker, Ogdensburg, addressed the Medical Society of the County of St. Lawrence in Potsdam November 2 on "Surgery of the Chest" and "Delivery of the Occiput Through a Presenting Cervix" respectively.

New York City

New Officers of Rockefeller Institute.—Dr. Warfield T. Longcope, Baltimore, was elected president of the board of scientific directors of the Rockefeller Institute for Medical Research at a meeting October 28. He succeeds the late Dr. Charles R. Stockard. Dr. Ross G. Harrison, New Haven, Conn., was elected a member of the board.

Society News.—A symposium on empyema was presented before the Brooklyn Thoracic Society November 24 by Drs. William H. Field, Henry W. Louria, Herbert C. Maier and Harry B. Reibstein.—At the first fall meeting of the International Spanish-Speaking Association of Physicians November 10 the speakers were Drs. Felipe Carranza, Buenos Aires, on "Treatment of Cancer of the Rectum"; Irving W. Potter, Buffalo, "Prevention of Maternal Deaths," and Nathaniel M. Levin, Philadelphia, "Speech Following Radical Removal of the Larynx."

Dr. Rose Honored.—Mary Swartz Rose, Ph.D., professor of nutrition, Teachers College, Columbia University, received the annual award of the Associated Grocery Manufacturers of America at the recent annual convention in New York. Dr. Rose was honored, the citation said, in recognition of her contributions to the science of nutrition, the part she has played in the dissemination of scientific information concerning foods, her authorship in this field and her outstanding career as a teacher of others who teach nutrition. Dr. Rose is a member of the Council on Foods of the American Medical Association.

Lectures to the Laity.—The New York Academy of Medicine began its fifth annual series of lectures to the laity November 30 with an address by Dr. Abraham Myerson, Boston, on "The Inheritance of Mental Disease." The series will continue as follows:

Dr. Richard H. Hutchings, Utica, N. Y., The Ascent from Bedlam, December 28.
Dr. Paul Reznikoff, New York, The Story of Our Knowledge of the Blood, January 25.
Drs. Chevalier Jackson and Chevalier L. Jackson, Philadelphia, The Romance of Bronchoscopy, February 29.
Dr. Thomas M. Rivers, New York, The Story of the Viruses, March 28.
Dr. Perrin H. Long, Baltimore, Chemical Warfare Against Disease, April 25.

Knapp Hospital Merged with Columbia.—Announcement is made of the merger of the Herman Knapp Memorial Eye Hospital with the Columbia-Presbyterian Medical Center. The hospital activities and care of patients now carried on by the Knapp Hospital at 500 West Fifty-Seventh Street will be taken over by the Presbyterian Hospital and the Vanderbilt Clinic. The hospital's assets and funds will be conveyed to Columbia and will be administered as the Knapp Memorial Foundation in Ophthalmology, the income of which will be used for graduate study, teaching and research in ophthalmology. The Herman Knapp Memorial Eye Hospital was founded in 1869 by Dr. Knapp as the New York Ophthalmic and Aural Institute. In 1909 Dr. Knapp was succeeded as executive surgeon by his son Dr. Arnold Knapp, and in 1913 the hospital became the Herman Knapp Memorial Eye Hospital with a new building situated near Columbia University College of Physicians and Surgeons. More than 800,000 patients have been treated at the hospital, 730,000 in the outpatient department and 70,000 inpatients, 76 per cent of whom were treated free, it was stated in the announcement. Dr. Herman Knapp was professor of ophthalmology at the University of Heidelberg, Germany, before he came to the United States in 1868. He died in 1911.

OHIO

The Annual Lower Lecture.—The second annual Lower Lecture of the Academy of Medicine of Cleveland was delivered November 17 by Dr. George H. Whipple, Rochester, N. Y., in the Cleveland Medical Library auditorium. Dr. Whipple's subject was "Hemoglobin Building in Anemia with Particular Reference to Iron."

Toledo University Institute.—The Sixth Annual Postgraduate Day of the Medical Institute of Toledo University was held November 3. The lecturers were Drs. Willard O. Thompson and Harry E. Mock, Chicago, who made three addresses each. Dr. Thompson's subjects were: "Treatment of Undescended Testes and Hypogonadism," "Treatment of Addison's Disease" and "Treatment of Toxic Goiter." Dr. Mock's were: "Treatment of Injuries with Special Attention to Lacerations and Tendon Sutures," "Treatment of Shock" and "Treatment of Head Injuries."

Personal.—Dr. Elmer G. Horton, who recently retired as clinical professor and chairman of the department of pediatrics at Ohio State University College of Medicine, Columbus, was honored at a dinner October 19 attended by 270 Ohio physicians and guests. Mr. Horace S. Kerr, Columbus attorney, was toastmaster, and the speakers included William McPherson, LL.D., acting president of the university, Drs. Elijah J. Gordon, John W. Wilce and Harry E. LeFever.—Dr. William K. Ruble, Wilmington, health commissioner of Clinton County since 1921, has retired.—Dr. Albert Graeme Mitchell, Cincinnati, has been appointed a member of the committee on education of the National Foundation for Infantile Paralysis.

PENNSYLVANIA

Outbreak of Scarlet Fever.—Schools were closed November 14-27 in Chester because of an outbreak of scarlet fever. More than sixty cases had been reported up to November 16. Seven of the patients were adults.

Postgraduate Day in Harrisburg.—A Postgraduate Day was held at the Harrisburg Academy of Medicine, Harrisburg, November 16, with the following speakers:

- Dr. Charles C. Higgins, Cleveland, Management of Patients with Renal Lithiasis.
- Dr. Alexander H. Colwell, Pittsburgh, Intrathoracic Tumors.
- Dr. Randle C. Rosenberger, Rahns, Interesting Facts Concerning Viruses and Viral Diseases.
- Dr. George P. Müller, Philadelphia, Surgical Treatment of Peptic Ulcer.

After a dinner at the Harrisburg Country Club Dr. Colwell spoke on "The House in Order" and Dr. Rosenberger, "Students I Have Met, or Trials and Tribulations of a Teacher."

Philadelphia

Personal.—Detlev W. Bronk, Ph.D., director of the Eldridge R. Johnson Foundation for Medical Physics and of the Institute of Neurology, University of Pennsylvania School of Medicine, has been appointed managing editor of the *Journal of Cellular and Comparative Physiology* of the Wistar Institute of Anatomy and Biology. He succeeds Edmund Newton Harvey, Ph.D., Princeton University, Princeton, N. J.

Medical Economics and Health.—The Philadelphia County Medical Society held a "health and medical economics night" November 8 with the following speakers: Dr. John J. Shaw, state secretary of health, on "Activities of the Department of Health of the Commonwealth of Pennsylvania"; Hon.

J. William Ditter of Montgomery County, "The Congressman Looks at the Doctor," and Dr. Arthur C. Christie, Washington, D. C., "The Physician's Responsibility for Medical Progress."

Annual Women's Cancer Forum.—The annual cancer forum under the auspices of the Women's Auxiliary of the Lankenau Hospital Research Institute was held at the Bellevue-Stratford November 28-29. The auxiliary was assisted by District No. 1 of the Pennsylvania State Nurses Association, with the cooperation of various health and medical organizations. Several groups presented exhibits on facts and research into the cancer problem. One session, was devoted to seminars led by physicians interested in special phases of cancer. Among out of town speakers was Harold S. Burr, Ph.D., New Haven, Conn., on "Electricity in Cancer."

Pittsburgh

Hospital News.—Montefiore Hospital held its annual "Scientific Day" November 18 with Dr. Charles R. Austrian, Baltimore, as the guest speaker. Short papers and cases were presented at the hospital during the day and Dr. Austrian spoke in the evening at the Concordia Club on "Diagnosis and Treatment of Chronic Nontuberculous Pulmonary Infections."

Society News.—Speakers before the Pittsburgh Urological Association November 13 were Drs. Isaac L. Ohlman, on "Carcinoma of the Ureter"; David H. Ruben, Washington, Pa., "Carcinoma of the Ureter; Ten Year Cure" and Howard L. Tolson, Cumberland, Md., "Prostatic Resection with a Modification of Young's Punch."—At a meeting of the Pittsburgh Surgical Society November 17 the speakers were Drs. John W. Shirer on "Preliminary Report on Peritoneoscopy; A New Diagnostic Method for Diseases of the Abdominal Cavity"; Dominic N. Di Silvio and Morris A. Slocum, "A Survey of 695 Herniographies," and John W. Fredette, "Chronic Dislocations of the Shoulder Joint with Special Reference to Technic of Operation for Repair."

RHODE ISLAND

Changes in Hospital Superintendents.—Dr. Dennett L. Richardson has resigned as superintendent of the Charles V. Chapin Hospital, Providence, to become superintendent of the Rhode Island Hospital, Providence, effective January 1. Dr. Richardson will succeed Dr. William O. Rice, who has resigned to take up other work.

Society News.—Drs. Champ Lyons, Boston, and Samuel Morein addressed the Providence Medical Association November 6 on "Chemotherapy and Immunology of Pyogenic Infections" and "Newer Aspect of the Medical Treatment of Gastric and Duodenal Ulcers" respectively. Dr. Allen Greenwood, Boston, was the speaker October 2 on "Eye Diseases Related to General Medicine and Surgery."

Course in Psychiatric Nursing.—The Emma Pendleton Bradley Home, East Providence, announces a postgraduate course in the practical nursing care of neuropsychiatric disorders of childhood. The course will run through twelve weeks beginning the first of January, April, July and October and will be limited to two nurses for each period. Details may be obtained from Dr. Arthur H. Ruggles, superintendent; Dr. Charles Bradley, medical director, or Kathleen Thornton, R.N., director of nursing. The Bradley Home is a fifty bed hospital dealing exclusively with neurologic and behavior disorders of children under 13 years of age.

TENNESSEE

Monument to a Family Doctor.—A monument to the memory of Dr. William P. Moore Jr., Portland, Tenn., who served the community for about fifty years, was unveiled October 29. The memorial was erected through the contributions of his patients and friends and dedicated with an address by Dr. William D. Haggard, Nashville. Dr. Moore died in 1932, aged 75.

Personal.—Dr. Bedford F. Peterson, assistant superintendent of the Eastern State Hospital, Knoxville, has been appointed superintendent of the Western State Hospital near Bolivar, it is reported.—Dr. William D. Martin, head of the division of criminal insane at Central State Hospital, Nashville, has been appointed superintendent of the Eastern State Hospital, Knoxville; he succeeds Dr. Oscar S. Hauk, who was transferred to the central institution as superintendent.

Conference of Southern Pathologists.—The Sixth Conference of Southern Pathologists was held at the University of Tennessee College of Medicine, Memphis, November 20. The speakers were Drs. William R. Mathews, Shreveport, La., on

"T. Charles W. Duval, New Orleans, and Bacteriology as One Subject" and Washington, D. C., "The Present Day Status of Clinical Pathology and Problems of the Clinical Pathologist," and Ernest W. Goodpasture, Nashville, unusual infections of the intestine. Orren W. Hyman, Ph.D., dean of the medical school, spoke at the luncheon, and the group was entertained at dinner by Dr. Harry C. Schmeisser.

Regional Meeting.—The Middle Tennessee Medical Association held its semiannual meeting in Springfield November 16 with the following speakers, among others:

- Dr. Nathaniel S. Shofner, Nashville, The Factors of Safety in Thyroid Surgery.
- Dr. Robert B. Gaston, Lebanon, Pelvic Endometriosis.
- Dr. Albert Weinstein, Nashville, Experiences with the Use of Sulfanilamide in the Treatment of Undulant Fever.
- Dr. Roscoe C. Kash, Lebanon, Observations on the Transmission of Infantile Paralysis.

TEXAS

Dallas Clinical Conference.—The Dallas Southern Clinical Society announces the following speakers for its twelfth annual Spring Clinical Conference to be held March 11-14 at the Hotel Adolphus:

- Dr. Marion A. Blankenhorn, Cincinnati, medicine.
- Dr. Chester S. Keefer, Boston, medicine.
- Dr. Warren H. Cole, Chicago, surgery.
- Dr. Frank E. Adair, New York, surgery, tumors.
- Dr. Clay Ray Murray, New York, fractures, traumatic surgery.
- Dr. John W. Harris, Madison, Wis., obstetrics and gynecology.
- Dr. Meredith F. Campbell, New York, urology.
- Dr. Frank E. Stevenson, Cincinnati, pediatrics.
- Dr. Tracy B. Mallory, Boston, pathology.
- Dr. Walter A. Fansler, Minneapolis, proctology.
- Dr. Parker Heath, Detroit, ophthalmology.
- Dr. Millard F. Arbuckle, St. Louis, otolaryngology, bronchoscopy.

District Meetings.—The Panhandle District Medical Society met recently in Lubbock with Dr. John W. Ames, Denver, as guest speaker on the scientific program on "Diagnosis of the More Common Skin Affections in Infants and Children," and in the evening on "A Close-up of Dictators."

—The Fourth District Medical Society held its annual meeting in Brady in October. Among the speakers on the scientific program were Drs. Oren H. Chandler, Ballinger, on "Liver Extract as a Therapeutic Agent"; Samuel Foster Moore Jr., San Antonio, "Newer Concepts in Estrogenic Therapy"; Victor E. Schulze, San Angelo, "Experiences in the Use of Sulfapyridine in Pneumonias," and Joseph F. McVeigh, Fort Worth, "Abnormal Cardiac Rates and Rhythms." Dr. Leopold H. Reeves, Fort Worth, president of the State Medical Association of Texas, spoke on "Present Day Problems of Organized Medicine" and Dr. Samuel E. Thompson, Kerrville, on "Socialized or Governmental Medicine."

WASHINGTON

New Health Officers.—Dr. Thomas H. Biggs, Chehalis, has been appointed district health officer for Grant and Douglas counties in Oregon and Dr. John B. Porter, formerly of Omaha, Neb., county health officer for Kitsap County to succeed Dr. Thomas C. Baldwin, Port Orchard.

State Health Survey.—Adolph J. Roth, Dr.P.H., formerly assistant professor of bacteriology and public health at Washington State College, Pullman, has been selected to conduct a health education survey under the auspices of the public health committee of the State Planning Council, according to *Northwest Medicine*. The survey is preliminary to establishment of health education recommendations for the public schools and state educational institutions.

WISCONSIN

Director of Mental Hygiene Appointed.—Dr. Gilbert E. Seaman, superintendent of the Winnebago State Hospital, has been appointed acting director of the division of mental hygiene in the new state department of public welfare established by the 1939 legislature. Morris G. Caldwell, Ph.D., Lexington, Ky., was appointed director of corrections.

Society News.—Drs. Willard L. Wood, Chicago, and Stanley J. Seeger, Milwaukee, addressed the Medical Society of Milwaukee County November 10 on "Arthritis" and "Some Technical Points in Pediatric Surgery" respectively.—A symposium on biliary surgery was presented before the Milwaukee Society of Clinical Surgery November 28 by Drs. Max Thorck, Chicago, and Armand J. Quick and William J. Carson, Milwaukee.

GENERAL

Sedgwick Medal Awarded to Dr. Parran.—The Sedgwick Medal, awarded annually by the American Public Health Association for distinguished service in public health, was presented at the recent annual meeting to Dr. Thomas Parran, surgeon general of the U. S. Public Health Service, Washington, D. C. The presentation was made by Dr. Milton J. Rosenau, director of the division of public health, University of North Carolina School of Medicine, Chapel Hill.

Congress on Pediatrics Postponed.—The American officers of the Fifth International Congress of Pediatrics, which was scheduled to be held in Boston Sept. 3-5, 1940, have decided that the international situation is such at present that it seems advisable to postpone the congress to an indefinite date. Dr. Henry F. Helmholz, Rochester, Minn., is president of the congress, Dr. Kenneth D. Blackfan, Boston, general secretary, and Dr. Charles F. McKhann, Boston, assistant secretary.

Radiological Society Meeting.—The annual meeting of the Radiological Society of North America will be held in Atlanta December 11-15 at the Atlanta-Biltmore Hotel, under the presidency of Dr. Raymond G. Taylor, Los Angeles. Refresher courses are to be conducted each morning throughout the week from 8:30 to 10:30. General sessions will be held in the mornings and separate sessions for diagnostic and therapeutic subjects in the afternoons. Dr. Francis Carter Wood, New York, will deliver the Carman Lecture Tuesday evening December 12 on "The Biological Effects of Radiation."

Infantile Paralysis Campaign.—The 1940 campaign for funds to fight infantile paralysis will again have two principal features, celebrations in honor of President Roosevelt's birthday, January 30, and the "March of Dimes," according to an announcement of the Committee for the Celebration of the President's Birthday. Mr. Keith Morgan, New York, is again national chairman and has appointed chairmen for all the states and territorial possessions. The celebrations will include dances, parties and entertainments of all kinds. A special feature will be the "March of Sports," a series of sports events under the general direction of Grantland Rice. The funds will be distributed on the same plan as last year, one half to the National Foundation for Infantile Paralysis and the other half to the localities where the money is raised.

Laboratory Directors Reorganize.—The Conference of Laboratory Directors, meeting during the annual convention of the American Public Health Association in October, changed its name and expanded under a new constitution and by-laws. The new name is Conference of State and Provincial Public Health Laboratory Directors. Full membership is limited to directors of official public health laboratories, while associate membership has been made available to the responsible assistants of directors of state and provincial laboratories and to the directors and responsible assistants in municipal and other official public health laboratories in the United States and Canada. Friend Lee Mickle, Sc.D., Wethersfield, Conn., was elected president; Mr. L. F. Ey, Columbus, Ohio, vice president, and Miss Katherine E. Cox, Charleston, W. Va., secretary.

Special Society Elections.—Dr. Gerald H. McMahon, Detroit, was elected president of the International Association of Police and Fire Surgeons and Medical Directors of Civil Service Commissions at the eighteenth annual meeting in New York in October. Dr. William M. Doody, Jersey City, N. J., was named vice president and Dr. John J. White, New York, secretary.—Dr. H. Earle Conwell, Birmingham, Ala., was elected president of the Clinical Orthopaedic Society at its recent annual session in Oklahoma City and Little Rock, Ark. Dr. Conwell was formerly secretary-treasurer of the society. Other officers are Drs. Charles A. Stone, St. Louis, vice president, and Myron O. Henry, Minneapolis, secretary-treasurer. The next annual session will be held in Milwaukee and Madison, Wis.—Dr. Jennings C. Litzberg, Minneapolis, was elected president of the Central Association of Obstetricians and Gynecologists at the annual meeting in Kansas City, Mo., in November. Drs. Thomas B. Sellers, New Orleans, and Edward P. Allen, Oklahoma City, were elected vice presidents and Dr. William F. Mengert, Iowa City, secretary. The 1940 convention will be in Indianapolis.—Dr. Leon Banov, Charleston, S. C., was chosen president of the International Society of Medical Health Officers at the annual meeting in Pittsburgh October 16; other officers are Drs. James R. Roberts, Hamilton, Ont., Canada, and Angel de la Garza Brito, Mexico City, vice presidents, and Dr. Irl C. Riggan, Richmond, Va., secretary-treasurer.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 4, 1939.

The Treatment of Air Raid Casualties

The organization for the treatment of the large number of air raid casualties expected among civilians has been described in previous letters. As no such raids have occurred we have had no experience with the arrangements, but the recent civil war in Spain seems to show that some modification is desirable. A well attended meeting of the Royal Society of Medicine was addressed by Dr. Trueta, formerly director of the department of surgery of the General Hospital of Catalunya, Barcelona, on the organization of hospital services for casualties due to the bombing of cities. He said that the numerous air raids on Barcelona had led the medical authorities to alter their organization as experience demanded. When it was found that first aid posts separate from the hospitals delayed complete treatment and increased mortality, they were abandoned. The wounds caused by the explosion of heavy bombs were severe and only few of the injured survived. Transportation was difficult, for movement increased shock and hemorrhage. Dispatch to the nearest hospital for complete treatment was the only measure that could save life. Those injured in the collapse of buildings from explosions also needed immediate assistance and even then the mortality was high. Persons should receive hospital treatment within two hours of the injury. Trueta strongly urged that first aid posts should be located in the hospitals. More than 30 per cent of the patients needed operation, and whatever facilitated rapid admission to a hospital contributed to success. The immediate intervention of the surgeon was the only useful form of first aid other than the application of a tourniquet for excessive bleeding. The application of splints, bandages and other forms of first aid at isolated posts was not only useless but dangerous because it delayed surgical treatment. A perfect circulation of ambulances was necessary. The casualties should be classified into five groups: (1) those who required immediate operation and who could not be sent out immediately; (2) those who required immediate operation and could be evacuated immediately; (3) those who needed immediate treatment and rest without operation and could not be evacuated; (4) those who after first aid could be transferred to the base hospital; (5) those who could go home after first aid.

In the classification room a colored card should be attached to each injured person. The director of the classification unit should know the number of surgeons and operating tables available and the specialty of each, so that the cases might be distributed according to capacity and with some regard to the pressure on each operator. Trueta's address made a great impression. It was thought that his principles would revolutionize treatment in air raid casualties.

Dispensing with Foreign Pharmaceutic Products

Many of the pharmaceutic products used in this country are of foreign origin, especially German. We must now depend on our own resources, which are greater than has been generally realized. During recent months, steps have been taken to meet any possible deficiency. The Association of British Chemical Manufacturers has published a long schedule showing that a British product equivalent to almost every foreign one is available. This should not be difficult, as most of the extensively advertised foreign preparations are only chemical substances masquerading under a proprietary name. The British ones are claimed as having the same essential composition as

the foreign or as having similar therapeutic properties and capable of replacing the foreign products. One firm has made arrangements to obtain supplies manufactured in the United States when its present foreign supply, which is considerable, has been exhausted.

Hospital for War Blinded Men

Before the outbreak of war it was decided at a conference between representatives of the fighting services, the Ministry of Pensions and the Ministry of Health to convert the convalescent home of St. Dunstan's Hospital into a war hospital for those who may be blinded in the present war. St. Dunstan's is known throughout the world for its care of those blinded in the great war. It was founded by Sir Arthur Pearson, a journalist who had become blind. The new hospital is situated on the downs near Brighton and has accommodations for 200 cases. It contains a small but perfectly equipped operating room in a part of the hospital erected at a cost of \$35,000, thanks to the generosity of Lord Nuffield. A staff from Moorfields, the principal ophthalmic hospital in the empire, is in residence. Plans are in hand to extend the hospital, if the need arises, and to enlarge the present school so that all the young blinded men may learn to read with their fingers, to typewrite, to look after themselves and to walk alone. The blinded men of the great war will hold out a helping hand to the young men who will join their ranks and take an active part as lecturers and teachers. There will be workshops and lecture rooms where trades, handicrafts and professions will be taught. The government will provide pensions for those blinded in the war and, as in the last war, St. Dunstan's will help them to recreate their lives. Of the 2,750 who were treated here, 2,000 are still alive.

The Evacuation of Sanatoriums for Tuberculosis

The council of the National Association for the Prevention of Tuberculosis has called attention to the danger of the evacuation of sanatoriums and hospitals for tuberculosis, which has taken place all over the country as part of the scheme to provide hospitals for the wounded. The patients have been distributed in their homes and many of them are infective to others. The council says that an infective case of pulmonary tuberculosis may in time cause as much harm as a bomb. Cases are known in which, after previous warning, a sanatorium has been evacuated at forty-eight hours' notice, and the council asks whether many of the beds might not still be used for tuberculous patients and evacuation done when the necessity arises. Another point is that tuberculosis will undoubtedly occur in members of the fighting forces, for whom sanatoriums should be available to the greatest possible extent.

PARIS

(From Our Regular Correspondent)

Oct. 29, 1939.

The Prognosis in Chronic Ascites

Cirrhotic ascites is rarely curable. Cases regarded as cures are generally remissions of long duration. Kervarec recently described before the Société de médecine de Paris the case of a woman aged 50 suffering from hypertrophic cirrhosis with ascites and enormous edema. She had undergone fifty-four punctures within eighteen months, in the course of which 779 quarts of peritoneal fluid were drained. The ascites had not reappeared for nine years. She had pneumonia in 1935 but in spite of hypertension (230/130) her condition was satisfactory. The prognosis of recent cirrhosis is more favorable than that of older cases, and the hypertrophic type heals more frequently than the atrophic. Icterus seriously aggravates the situation. Three kinds of symptoms signify the cure or evolu-

tion of ascites: First, the more or less rapid disappearance of portal hypertension is a factor which permits an improved outlook. Furthermore, the restoration of a normal relation between the blood serum and erythrocytes indicates a return to equilibrium in protein metabolism. In the third place, biologic tests show the persistence of hepatic insufficiency even after improvement that looks like a cure. Maillard's coefficient (Lanzenberg's acidosis coefficient) and urobilinuria remain quite high. On the other hand, experimental tests for galactosuria remain satisfactory.

The Rickettsias

In a recent session of the Société de pathologie exotique, Paul Giroud and R. Pauthier reproduced specimens of conjunctival cells in which it was difficult to distinguish the Rickettsias of classic morphology from the bacteria modified by phagocytosis, clearly a potential cause of error for those who study the connection between trachomas and Rickettsias. At the same meeting Etienne Burnet voiced his skepticism of the role the Rickettsias play in the study of trachomas. He believes that the trachoma agent is a corpuscular virus of the same type as those of psittacosis and acute lymphogranuloma, a point of view derived from the descriptions of Halberstadter and Prowasek. The recently described Rickettsias cannot be accepted, at least as Rickettsias. They differ too much from the micro-organisms for which this name was coined. Either they are not Rickettsias at all or they belong to a species other than those whose presence in typhus has been ascertained. Weigl, on the other hand, has proved that Rickettsias of the type of rocha limae have nothing to do with trachoma. The transmission of "Rickettsia-like bodies" recently achieved by Cuénod and Nataf from louse to louse or from louse to man and monkey seems to indicate that these bodies, whatever name they should bear in the nomenclature, are indeed trachoma agents (THE JOURNAL, November 25, p. 1977).

Nov. 4, 1939.

Strangulation of Intellectualism

The "scientific academies of the national socialist alliance of German university instructors" constitute the chief weapon which the national socialist party has created to transform the universities. The three existing academies of this kind, in Göttingen, Kiel and Tübingen, recently held their annual session in Munich, "capital of the movement," as it is now officially designated. Dr. Schultze, its leader, who was previously unknown, declared that "the alliance is the appointed trustee of the national socialist party at the universities to see that universities and scholarship are not only painted brown but really made over to fit the pattern of national socialism." In the official opening address of the Bavarian government, the demand was made that "scholarship should serve life and that the national socialist party was today's life. Whatever stood aloof from it was doomed to die and be destroyed, even if still arrayed in ostentatious garments." Schultze had also this to say: that the present struggle of scholarship was to liquidate the ideas of a defunct past generation that had corrupted German thinking. All dominant ideas of the past, medieval dogmatic theology as well as the rationalism of the Enlightenment, had one thing in common; namely, they were of foreign origin. In the middle ages the Germans had learned to feel fear; the Enlightenment, on the other hand, had merely supplied the new ideas of equality and freedom, the former contrary to nature, the latter knowing no restraint. German scholarship, he said, had failed the people because it had emphasized objectivity so much that race, life, country and "weltanschauung" had been lost sight of. The German uni-

versity of the last years was not to be compared with that of former years. He concluded with the statement that "German scholarship and German universities would become either thoroughly national socialist or cease to exist."

Another glimpse into how German cultural life is molded and reconstructed to serve Nazi purposes can be caught from Goebbels's remarks in keeping with his recent utterances on the "intellectuals." He delivered a speech in Berlin's palace of sports on the occasion of a district student gathering, in which he discussed the relation of the intellectual worker to the people and, in particular, the distinction between intelligence and intellectualism. He inveighed against the intellectualist, meaning, chiefly, university teachers and specialists who did not sufficiently bend the pregnant hinges of their knees to nazism, in whom reason had overgrown character and knowledge had destroyed faith. He called them "strolling scholars of our social life," representing not the upper ten thousand but the lower ten thousand, against whom one had to protect oneself. Perhaps it is, he said, the highest political duty to obey faithfully even when reason and knowledge from the point of view of the individual directs a different course. Of course, many of the older generation would regard this demand as impossible. However, the majority of the German people already possessed this discipline. German students should consider it their great political obligation to help achieve the fulfilment of this ideal. Intellectualism would then die a natural death. It was the duty of every intellectual worker, as of every other German, to obey Hitler. Utterances such as these by men high in the council of the totalitarian party on cultural life and the universities naturally affect also physicians and the pursuit and practice of medicine.

Control of the Use of Alcohol and Tobacco

The fight on alcohol and tobacco has been repeatedly reported in these columns (see THE JOURNAL, August 3, p. 1144). Lack of uniform regulations seems to have made necessary the creation of a "government bureau against the dangers of alcohol and tobacco," the administration of which was assumed by Dr. Conti, government health leader. It takes over the functions discharged previously by the government work union for combating alcoholism and by the organizations associated with it. The new bureau will also deal with the control of opiates and hypnotics. Its activities will include publicity and propaganda, the training of workers, the support of the internal administration of the related bureaus and the systematic organization and guidance of activities in relation to all persons who are ill and endangered. Furthermore, the bureau is to promote the production of sweet cider and all nonalcoholic beverages.

The regulation has been put in force recently in Germany prohibiting, in the advertising of tobacco merchandise and alcoholic beverages, reference in any form or fashion to what might create a public impression that hygienic values were connected with the use of tobacco and alcohol. Smoking is prohibited in government bureaus; similar prohibitions concern the army. Moreover, the head of Berlin's police department has requested automobile drivers to refrain from smoking because it increases traffic hazards. This police order will create criminal negligence for drivers who are involved in a collision while engaged in smoking.

According to official statistics, the consumption of beer increased in 1938 by about 4,250,000 hectoliters (1 hectoliter equals 26.4 U. S. gallons) to a total of 46,940,000 hectoliters, equivalent to a per capita increase from 62.9 to 68.8 liters, and the consumption of brandy by 65,000 hectoliters to a total of 327,000 hectoliters; that is, to 1.21 liters per capita of population. In general the increased buying power on the part of the public was accompanied with increased consumption of stimulants. The use of cigarets rose from 609 to 676 per

capita, that of coffee from 2.1 to 2.3 Kg. A decrease was noticed only in the consumption of wine, after the considerable surplus of the record vintages of 1934 and 1935 had been gradually consumed.

Prophylaxis Against Infection in Children's Homes

New directions have been officially released for the more effective protection of children sent away for recreational purposes. Before children are admitted in recreational homes or in private families they are to be medically examined twice, once about two months, the second from one to two days, before departure. At the same time, active vaccination against diphtheria of all children is recommended, the first about two months, the second a month before departure. Immediately on arrival the children should again be medically examined. All suspected children should be segregated until clarification of the diagnosis. Furthermore, all children are to be examined at least once a week during this vacation sojourn by a physician or a trained assistant for infectious diseases. The same precautionary examinations apply to the personnel of the homes and must be performed once every four weeks.

Students Conscripted into Harvest Fields

German students had to work in the harvest fields this year. The universities shortened the summer semester to enable the harvesting for the benefit of the eastern section of the country. The work period lasted from four to six weeks. All students had to serve no matter in what semester they were enrolled or for what course of studies they were registered. The only exemption allowed was the need of urgent preparations for an examination or some similar necessity. As Dr. Scheel, student leader for the reich, declared in his proclamation, it was the duty of German students to help secure their daily bread and make secure their frontiers and to feel enthusiasm for the fuhrer and the German people. Every student was furnished with a work certificate, which he had to present when enrolling for the winter semester. Female students had to assist farm women or conduct harvest kindergartens for young children of peasants in the day time, while their parents were at work. At the end of July, 46,000 students were engaged in eastern Germany in agricultural or harvest work. They were protected by sufficient insurance against sickness and accidents.

Statistics of the Sick Funds

At the suggestion of the reich's public health department, a uniform system of voluntary statistics has been organized for the sick funds. The statistical department of the reich has just published the first results covering the year 1937. Eighty-seven sick funds, with a membership of 4,380,000, reported 1,090,000 male and 680,000 female illnesses. Exclusive of accidents and injuries caused by external agencies, the diseases of men that involved inability to work and loss of working days appeared in the following frequency: influenza 9.1 per cent, muscular rheumatism 5.1 per cent, bronchitis 4.4 per cent, furuncles, abscesses and so on 3.8 per cent, gastric diseases exclusive of ulcers 3.6 per cent, gastric and duodenal ulcers 3.4 per cent, organic cardiac diseases 3.2 per cent. Influenza, accounting also in the case of women for the greatest loss of working days, is represented by 9.6 per cent. Next in order are tonsillitis, pharyngitis and kindred inflammations with 4.5 per cent, organic cardiac diseases with 3.8 per cent, bronchitis with 3.5 per cent and neurasthenia and neuroses with 3.4 per cent.

Medical Training and Appointments

As reported in THE JOURNAL April 8, page 1401, a new medical curriculum has been decreed. Corresponding regulations governing appointments have now likewise been issued. Medical education has been reduced from eleven to ten semesters. The so-called practical year, which one had to serve after com-

pleting the final examinations in order to secure an appointment, has been abolished, effective April 1, 1940. The training course is now organized as follows: It begins with a course of six months attending and nursing patients before beginning university studies. The purpose is to eliminate the unfit. Pre-clinical studies follow in order and continue through four semesters. Successful completion is evidenced in preliminary examinations covering zoology, botany, chemistry, physics, anatomy and physiology. During the vacation periods of the two years the student must work six weeks either in a factory or on a farm. Clinical studies last six semesters. During the vacations, medical students are required to serve twice for three months each as hospital attendants. Provisions have been made so that students may take the state examination within four weeks (formerly it occasionally took six months). On passing the state examination, one is at once granted an appointment. The right to private practice is not allowed, however, until the young physician has served an obligatory year of internship in a hospital and a fourth of a year as assistant or substitute of a sick physician with a rural practice. Students unable to bear arms and female medical students must serve in the German Red Cross or do health welfare work in connection with the Hitler youth movement.

Organization of Committee to Combat Rheumatism

Professor Reiter, president of the public health department of the reich, has organized a committee of specialists to plan measures for protection against rheumatic diseases. Special attention is to be given to the early treatment and timely care of rheumatic persons. It is planned gradually to create effective organizations throughout the nation.

AUSTRALIA

(From Our Regular Correspondent)

Nov. 8, 1939.

Control of the Flying Doctor Service

The Australian Inland Mission Board of the Presbyterian church recently handed over control of the "flying doctor" services at Cloncurry (Queensland) to the Australian Aerial Medical Services. Queensland is the last of the states to register an association not for profit to form a link in a chain of aerial medical services conducted by this organization throughout Australia. The "flying doctor" scheme, as developed originally by the Australian Inland Mission at Cloncurry, is now well established as the most efficient way in which our "outback" settlers may be brought within reach of medical aid. Its development will stand for all time as a monument to Rev. John Flynn, whose dream it was. He realized the terrible isolation when illness or accident overtakes these people. He was familiar with the tragic stories of infants who had died in their mothers' arms on the heart breaking journey of hundreds of miles to the nearest doctor; of the men who, gravely injured in the course of their work, were faced with death where they lay from lack of skilled attention or being killed by the awful journey to a hospital over rough bush tracks. He realized how men shrank from the risk of taking a wife and children out there, with the result that much of our outback is inhabited by men alone. Without the influence of white women and children there seems inevitably to be a decline in those cultural and moral standards which are essential to satisfactory permanent settlement of our back country.

Mr. Flynn's inspiration to use an airplane as a means of transport and wireless as a means of communication between these outback people and their doctor is well known. The amazing thing about it is the clarity of that inspiration, conceived at a time (about 1912) when airplanes were unreliable and unsafe and wireless sets—especially transmitters—were hopelessly expensive and intricate. The airplane was improved

by commercial enterprise, and after years of experiment the wireless problem yielded to the genius of Alfred Traeger, encouraged and supported by Mr. Flynn and the Australian Inland Mission. At last in May 1928 the first aerial medical service base at Cloncurry, was formed. Since that time the Cloncurry base has gone forward steadily, meeting and conquering its difficulties as they arose and building up a tradition of service which holds the admiration of all who know it. It was found that the Cloncurry base could efficiently cover an area of 400 miles radius, that is, an area almost as large as New South Wales. So vast, however, is the sparsely settled part of Australia that there still remained thousands of isolated settlers far beyond the range of the mantle of safety spread by that base. It was obvious that at least six bases would be necessary to serve the whole of Australia's frontiers. A larger organization of national character was therefore formed to undertake the establishment of these bases. It was christened "Australian Aerial Medical Services." Under its auspices other bases have come into being and much valuable work has already been done in those areas.

The heart of an aerial medical service base is the mother radio station, situated close to the flying doctor's home. These stations are fairly powerful and send out excellent signals in voice so that the outback people listen to it just as easily as one does to a broadcast program. Scattered round the mother station are numerous pedal sets, the ingenious "transceivers" invented and built by Mr. Traeger. These small stations derive their main power from a generator driven by bicycle pedals and with them the owners are able to send clear signals in voice from distances of 700 miles and more. They have in reserve a remarkable instrument called an automatic transmitting keyboard for sending Morse code when atmospheric conditions are not suitable for voice. They are all thus kept in constant communication with the mother station and the doctor. Constantly at the disposal of the doctor is an airplane especially adapted to carry a patient on a stretcher in the cabin. The ambulance plane also carries wireless and so keeps the doctor in touch with his base and the rest of his large "practice" while he is out on a flight.

Several avenues of service are available with such organization: 1. Detailed advice as to treatment not only sets anxious hearts at rest in cases of minor illness but, when applied early, often prevents a major illness from developing. 2. A prompt call to the doctor, early diagnosis and quick, comfortable transport to a hospital, where efficient treatment can be given, are saving several lives each year in each of the areas now covered by the Aerial Medical Service. 3. Not the least valuable of these avenues involves no active work at all. The very presence in the district of the Aerial Medical Service base, able and willing to help in time of need, brings the outback people a sense of security hitherto unknown to them. 4. Wireless has broken down the isolation of the bush. Lonely women who do not see another white woman for months at a time can now converse in voice with their next door neighbor a hundred miles away. The receivers are used to receive broadcast programs and bring the news of the world to the most remote homes in the continent.

The Aerial Medical Service is rapidly developing in the back country a network of efficient communication and aerial transport facilities, such as landing ground and gasoline supplies—an interesting by-product of the purely medical work which is its mainspring.

Hydatid Disease in New Zealand

For nearly fifty years Sir Louis Barnett, emeritus professor of surgery, University of Otago, and chairman of the New Zealand Hydatid Research Committee, has concerned himself with an investigation of the high prevalence of hydatid disease in New Zealand. Now he has published in the *New Zealand*

Medical Journal a further report on the incidence of the disease and the progress of the prevention campaign. The figures for 1938 are slightly better than those for 1937, but it is not yet permissible to claim a definite diminution of hydatid incidence in New Zealand. Last year the Hydatid Registry recorded a total of 1,304 cases with 151 deaths in a population of 1,604,244. In 787 cases the site of the cysts was the liver, and in 260 the lungs were involved. The prevalence of hydatid cysts in farm animals, as shown by abattoir tables and field research observations, continues at an alarming height. In New Zealand there are approximately 31 million sheep and 4¼ million cattle. Barnett claims that more than half of those reaching adult life have their livers and lungs studded with cysts either of *Echinococcus* or *Tenuicollis* type or both. The prevalence of the adult hydatid worm (*Taenia echinococcus*) in the dog is also considered very high.

The prevention campaign has been intensified during the year, and notable advances have been made in the lecturettes, films, models and specimen demonstrations at most of the Agricultural Shows and at other suitable gatherings. Another move that has this year focused the attention of dog owners on the subject of hydatid disease, its prevalence and ill effects and its possible prevention, is the distribution by the government to all dog owners in the dominion, on the occasion of dog registration, of a supply of arecaline vermifuge tablets, which can be depended on, if properly used, to eradicate not only the hydatid parasite but also sundry other worms to which dogs are prone.

Reports on the results of this action have been almost universally favorable but, as was only to be expected, there have been adverse comments receiving much attention in the press. These allegations, although unwarranted, have increased the number of dog owners who refuse or neglect to dose their dogs. At present they are under no legal obligation to do so; but the Hydatid Research Committee strongly urges that the two absolutely essential procedures in the campaign of hydatid eradication should be made compulsory by law. These procedures are (1) the regular administration of an approved vermifuge to all dogs and (2) the prohibition against the feeding of dogs on the raw livers and lungs of sheep and cattle.

Through the medium of the Hydatid Registry of the Royal Australasian College of Surgeons, clinical research on the problem of hyatids in Australia and New Zealand is also making headway, and with helpful cooperation from the community it should soon be possible to have the disease under efficient control.

Marriages

EUGENE AMOS HOLLAND to Miss Mary Frances White, both of Fairmont, W. Va., at Hot Springs National Park, Ark., August 17.

JOHN WILLIAM DIDCOCK, Shelbyville, Tenn., to Miss Joy Carrier at Mortons Gap, Ky., October 7.

SAMUEL EUGENE FIELD, Centreville, Miss., to Miss Mildred Elizabeth Ruoff of Jackson, October 27.

MICHAEL D. MASSENGILL JR. to Miss Mary Linda Rector, both of Kingsport, Tenn., October 8.

BEN BESHOR, Trinidad, Colo., to Mrs. Olive Waldrip of Los Angeles at Raton, N. M., October 3.

CARL FREDERICK NEUHOFF to Miss Hazel Louise Davenport, both of Peoria, Ill., October 14.

JULIA S. MEHLMAN to Maj. Frederick W. Greenhut, both of New York, November 11.

WIXOM S. SIBLEY to Miss Katherine Pickett, both of San Francisco, November 9.

NATHAN J. DAVIDOV to Miss Elsie Zerwitz, both of Baltimore, September 27.

JOHN R. MOODY to Miss Kathaleen Daniels, both of Erwin, Tenn., October 14.

Deaths

Charles Clifton Browning, San Marino, Calif.; University of Missouri School of Medicine, Columbia, 1883; member of the California Medical Association; professor emeritus (tuberculosis) at the College of Medical Evangelists, Loma Linda; fellow of the American College of Physicians; for many years a director of the National Tuberculosis Association; member of the American Clinical and Climatological Association; past president of the California Tuberculosis Association and the Los Angeles County Medical Association; served during the World War; formerly chief of the staff of the tuberculosis service, Los Angeles County Hospital; aged 78; died, September 28, of pneumonia.

Ashley Walker Morse Ⓢ Butte, Mont.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; member of the American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological and Otolological Society and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; for many years secretary of the Montana Academy of Oto-Ophthalmology; past president of the Silver Bow County Medical Society; consultant to St. James Hospital; aged 56; died, October 12, at Lansing, Mich., of pneumonia.

David Baker Ⓢ Colonel, U. S. Army, retired, Waltonville, Ill.; Barnes Medical College, St. Louis, 1893; fellow of the American College of Surgeons; veteran of the Spanish-American War; was commissioned an assistant surgeon in 1898, a captain in the medical corps of the U. S. Army in 1903 and rose through the various ranks to that of colonel in 1917; retired in 1935 by operation of law; aged 68; died, September 8, at Fort Sam Houston, Texas.

Jacob Usry Ray, Woodstock, Ala.; University of Tennessee Medical Department, Nashville, Tenn., 1893; member of the Medical Association of the State of Alabama and formerly treasurer; for many years secretary of the Alabama Association of Railroad and Industrial Surgeons; at one time postmaster; past president of the Bibb County Medical Society; aged 75; died, October 5, of myocarditis, arteriosclerosis and hypertension.

Howard Brownlee Hamilton Ⓢ Omaha; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; professor emeritus of pediatrics at the University of Nebraska College of Medicine; past president of Omaha-Douglas County Medical Society; member of the American Academy of Pediatrics; aged 64; died, October 12, of bilateral bronchopneumonia.

Bayard G. Keeney Ⓢ Shelbyville, Ind.; Medical College of Ohio, Cincinnati, 1902; fellow of the American College of Physicians; past president and secretary of the Shelby County Medical Society; health officer; for many years member of the city board of education; aged 63; died, October 11, at Fort Wayne of coronary occlusion while attending the state medical meeting.

Francis Washington Sovak Ⓢ New York; University and Bellevue Hospital Medical College, New York, 1911; clinical professor of obstetrics and gynecology at his alma mater; fellow of the American College of Surgeons; on the staffs of the Bellevue Hospital and the Misericordia Hospital; aged 54; died, October 27, in the Midtown Hospital.

Archibald Ray Knode Ⓢ Omaha; University of Nebraska College of Medicine, Omaha, 1904; formerly associate professor in the department of otorhinolaryngology at his alma mater; member of the American Academy of Ophthalmology and Otolaryngology; on the staff of the Immanuel Hospital; aged 57; died, October 11, of coronary thrombosis.

George Joseph Waggoner Ⓢ Ravenna, Ohio; University of the City of New York Medical Department, 1890; past president and secretary of the Portage County Medical Society; formerly member of the city board of health; on the staff of the Robinson Memorial Hospital; aged 74; died, October 7, of pulmonary thrombosis.

Wilbert Arthur Hobbs Ⓢ East Liverpool, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; fellow of the American College of Surgeons; Spanish-American War veteran; aged 77; on the staff of the East Liverpool City Hospital, where he died, October 17, of cerebral hemorrhage.

Austin Funk Ⓢ Jeffersonville, Ind.; University of Louisville (Ky.) Medical Department, 1900; served during the World War; formerly secretary of the Clark County Medical

Society; aged 65; died, October 24, in the Clark County Memorial Hospital of skull fracture received in an automobile accident.

Oscar Brunk Funkhouser Ⓢ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; Northwestern University Medical School, Chicago, 1909; aged 53; died, October 17, in the Washington Boulevard Hospital of mitral insufficiency.

Robert H. Trimble, Mount Sterling, Ohio; Starling Medical College, Columbus, 1894; member of the Ohio State Medical Association; county health officer; formerly mayor; past president of the school board; aged 69; died, October 18, in the Grant Hospital, Columbus, of carcinomatosis.

Fred Lawwill Rhodes, Massillon, Ohio; Ohio State University College of Medicine, 1916; served during the World War; formerly on the staff of the Massillon State Hospital; aged 49; died, October 10, in the White Cross Hospital, Columbus, of obstruction of the esophagus.

Harry Obadiah Knight Ⓢ Galveston, Texas; University of Texas School of Medicine, Galveston, 1907; member of the American Association of Anatomists; professor of anatomy at his alma mater; aged 58; died, October 5, in the John Sealy Hospital of a self-inflicted bullet wound.

Charles Edward Miller, Muncie, Ind.; Miami Medical College, Cincinnati, 1898; member of the Indiana State Medical Association; past president of the Delaware-Blackford Counties Medical Society; aged 69; died, October 17, of bronchopneumonia and heart disease.

Ralph Edgar Weller, Electra, Texas; University Medical College of Kansas City, Mo., 1904; member of the State Medical Association of Texas; fellow of the American College of Surgeons; served during the World War; aged 67; died, October 12, of cerebral hemorrhage.

Eugene Carl Roemele, Frankfort, Ky.; Hospital College of Medicine, Louisville, 1897; member of the Kentucky State Medical Association; county health officer; at one time medical director of the State Reformatory; aged 62; died, October 14, of angina pectoris.

James Buchanan Lightfoot, Miami, Okla.; Memphis (Tenn.) Hospital Medical College, 1905; member of the Oklahoma State Medical Association; aged 75; died, October 5, in the Miami Baptist Hospital of arthritis following an injury received in a fall.

Eugene Frederick Hauck, Clayton, Mo.; St. Louis Medical College, 1880; member of the Missouri State Medical Association; for many years medical director of St. Louis Mutual Life Insurance Company; aged 82; died, October 8, of pyelitis and heart disease.

Jacob John Minke, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; served during the World War; physician in chief to the Oak Forest (Ill.) County Infirmary; aged 56; died, October 1.

George Elias Boulos, Hazard, Ky.; University of Louisville (Ky.) School of Medicine, 1927; on the staff of the Hurst-Snyder Hospital; aged 36; was found dead, October 20, at his office in Louisville of illuminating gas poisoning, self administered.

Edwin Merville Bennett, Paris, Ill.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; member of the Illinois State Medical Society; served during the World War; aged 72; died, October 14, of coronary thrombosis.

Reuben Harrison Mast Ⓢ Myrtle Point, Ore.; University of Oregon Medical School, Portland, 1924; medical director of the Mast and Wilson Hospital; aged 44; died, October 8, as a result of an accidental fall from a hotel window in Portland.

Granville E. Dickinson Ⓢ Upper Fairmount, Md.; University of Pennsylvania Department of Medicine, Philadelphia, 1874; an Affiliate Fellow of the American Medical Association; aged 87; died, October 14, of acute dilatation of the heart.

Moza West Hurt, Mayfield, Ky.; University of Louisville (Ky.) Medical Department, 1911; member of the Kentucky State Medical Association; on the staff of the Mayfield Hospital; aged 54; died, October 6, of cerebral embolism.

John Jacob Kirschenmann Ⓢ Brooklyn; Long Island College Hospital, Brooklyn, 1924; on the staff of the Norwegian Lutheran Deaconess Home and Hospital; aged 40; died, October 5, in Phoenix, Ariz., of tuberculosis of the lungs.

Carlyle Walter Dewey, Conneaut, Ohio; Cleveland Homeopathic Medical College, 1910; city health officer; member of the state medical board; formerly county coroner and member of the board of education; aged 58; died, October 22.

William Walter Wyatt, Peoria, Ill.; Illinois Medical College, Chicago, 1903; member of the Illinois State Medical Society; served the Methodist Hospital in various capacities; aged 74; died, October 22, of coronary thrombosis.

Willis Dowd Gilmore, Phoenix, Ariz.; University of North Carolina School of Medicine, 1903; tuberculosis consultant for the state board of health; aged 61; died, October 19, in Ann Arbor, Mich., of heart disease.

Frederick Philip Mann, Valley Falls, Kan.; St. Louis University School of Medicine, 1904; served during the World War; on the staff of St. Francis Hospital, Topeka; aged 61; died, October 16, of cerebral hemorrhage.

James M. Erwin, Calhoun, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1898; member of the Medical Association of Georgia; aged 75; died, October 19, of injuries received when struck by an automobile.

Albert J. Howell, Bay Port, Mich.; Detroit College of Medicine, 1896; member of the Michigan State Medical Society; aged 70; died, October 7, in the Hubbard Memorial Hospital, Bad Axe, of angina pectoris.

Arthur P. Shearburn, Walnut, Ill.; Chicago Homeopathic Medical College, 1893; member of the school board and formerly mayor; aged 77; died, October 8, in the Julia Rackley Perry Memorial Hospital, Princeton.

Franklin Fletcher Dunham, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1913; aged 52; died, October 31, at the Deer Lodge (Man.) Hospital of coronary thrombosis and chronic pericarditis.

Francis Marion Sanders, Herrin, Ill.; St. Louis College of Physicians and Surgeons, 1904; member of the Illinois State Medical Society; was a member of the school board; aged 72; died, October 19, of heart disease.

James Wilson Cowart, Walden, Ga.; Tulane University of Louisiana School of Medicine, New Orleans, 1894; member of the Medical Association of Georgia; aged 69; died, October 11, of aplastic anemia.

Perry Oliver Englerth, North Judson, Ind.; Kentucky School of Medicine, Louisville, 1896; member of the Indiana State Medical Association; aged 65; died, October 25, of coronary thrombosis.

Adolph O. Speckhard, Bay City, Mich.; Fort Wayne College of Medicine, 1896; member of the Michigan State Medical Society; aged 75; died, October 19, of benign hypertrophy of the prostate.

William Orlando Durham, Moxeys, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893; aged 70; died, October 5, of cerebral thrombosis, arteriosclerosis and hypertension.

Johanna Baptistella Leo, New York; Woman's Medical College of Pennsylvania, Philadelphia, 1897; member of the Medical Society of the State of New York; aged 75; died, October 20.

William F. Cleveland, Evansville, Ind.; Kentucky School of Medicine, Louisville, 1892; member of the Indiana State Medical Association; formerly state senator; aged 83; died, October 10.

Harry Alonzo Lewis, Continental, Ohio; Toledo Medical College, 1896; member of the Ohio State Medical Association; formerly mayor; aged 80; died, October 7, of coronary thrombosis.

Robert Brown, San Francisco; College of Physicians and Surgeons of San Francisco, 1911; aged 61; died, September 13, in St. Francis Hospital of coronary occlusion and arteriosclerosis.

William Stanley Reilly, Joliet, Ill.; St. Louis University School of Medicine, 1917; served during the World War; aged 47; died, September 26, in the Veterans Administration Facility, Hines.

Charles T. Granger, Rochester, Minn.; Hahnemann Medical College and Hospital, Chicago, 1892; aged 69; died, October 4, of cardiac decompensation, arteriosclerosis and bronchopneumonia.

Anton Philip Freund, Chicago; Bennett Medical College, Chicago, 1911; served in the U. S. Public Health Service; on the staff of the American Hospital; aged 76; died, October 15.

Guy Watts Wagner, Chicago; Northwestern University Medical School, Chicago, 1899; served during the World War; on the staff of the Henrotin Hospital; aged 65; died, October 7.

Philip Berry Thomas, Decatur, Ind.; Chicago Medical College, 1885; for many years secretary of the city board of health; aged 79; died, September 20, of cerebral hemorrhage.

Arthur Miller Northrup, Wilkes-Barre, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; aged 61; died, October 3, in the Pembroke (Ont.) Hospital.

Harry J. Phillips, Louisville, Ky.; University of Louisville Medical Department, 1893; aged 67; died, October 10, in the Kentucky Baptist Hospital of a streptococcal infection.

Oliver P. Morton Ford, Centerville, Ind.; Medical College of Ohio, Cincinnati, 1889; aged 75; died, October 25, in the Reid Memorial Hospital, Richmond, of heart disease.

Louis I. Melnick, Los Angeles; University of Vermont College of Medicine, Burlington, 1919; aged 53; died, September 12, of coronary occlusion and chronic myocarditis.

Frances Pearl Frank Zumwalt, Tulare, Calif.; College of Physicians and Surgeons, Los Angeles, 1917; aged 45; died, September 13, of metastatic carcinomatosis.

Clarence Gilliam Reno, Summit, Ky.; University of Louisville (Ky.) Medical Department, 1897; served during the World War; aged 66; died, October 5.

William Duff Forrest, Halifax, N. S., Canada; Halifax Medical College, 1898; L.R.C.P., London, and M.R.C.S., England, 1901; died, September 12.

Wyllis A. Silliman, Alameda, Calif.; University of the City of New York Medical Department, 1886; aged 81; died recently of asphyxiation due to submersion.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Cannon's Salve.—Dr. J. Cannon Salve Co., Ltd., Petoskey, Mich. Composition: Essentially a lead compound in a fatty base. For frozen feet, eczema, mad dog bite, blood poison, boils, etc. Fraudulent therapeutic claims.—[N. J. 29774; March 1939.]

Dodd's New Discovery.—Stotts Medicine Co., West Memphis, Ark. Composition: Essentially water, sugar, alcohol, chloroform, oil of sassafras and menthol. Fraudulently represented as a cure for pneumonia, asthma, tuberculosis, and other lung and bronchial troubles.—[N. J. 29771; March 1939.]

Hauser Potassium Broth.—Modern Health Products, Inc., Milwaukee. Composition: Essentially ground dried plant materials including peas, carrot, onion, celery and alfalfa, with common salt. Misbranded because played up as a health product and because falsely represented to be a potassium preparation and a highly concentrated alkaline broth. Fraudulent therapeutic claims.—[N. J. 29765; March 1939.]

[An earlier Notice of Judgment (26484, May 1937) charging similarly fraudulent claims made for this and the two foregoing products was the subject of an extended article in the Bureau of Investigation Department of THE JOURNAL, June 19, 1937, p. 2155.]

Lal Tablets No. 2.—Lal Pharmacal Co., New York. Composition: Essentially acetophenetidin (about 2 grains per tablet), aspirin and caffeine. Misbranded because presence and amount of acetophenetidin were not declared and because the product was fraudulently represented as a remedy for la grippe.—[N. J. 29754; March 1939.]

Norwesco Rub.—McKesson & Robbins, Blumauer-Frank Division, Portland, Ore. Composition: A grease containing oil of eucalyptus. Fraudulently represented as efficacious in surface inflammations, croup, coughs, deep chest colds and incipient pneumonia.—[N. J. 29762; March 1939.]

Millertone.—J. S. Miller, Inc., New Jersey (town not given). Composition: Essentially ground senna leaves with small amounts of other plant material, including possibly buckthorn bark and gentian root. Fraudulently represented as virtually a cure-all.—[N. J. 29787; March 1939.]

Parlogen Tablets.—American Drug & Chemical Co., Minneapolis. Composition: Rochelle salt, starch and a small amount of a chlorine-liberating compound. Fraudulently represented as having antiseptic and germicidal action in "feminine hygiene."—[N. J. 29763; March 1939.]

[San-Tox] **Nurse Brand Blackberry Root and Ginger Compound.**—De Pree Co., Holland, Mich. Composition: Essentially extracts of plant material (including ginger), and a small amount of volatile oils (including cloves and nutmeg) with alcohol and water. Fraudulently represented as a cure for relaxed conditions of the bowels.—[N. J. 29793; March 1939.]

[San-Tox] **Nurse Brand Boil Salve.**—De Pree Co., Holland, Mich. Composition: Essentially zinc oxide and a small amount of carbolic acid in a specially prepared base. Fraudulently represented as effective in aborting incipient boils.—[N. J. 29795; March 1939.]

San-Tox Nurse Brand Flaxseed.—De Pree Co., Holland, Mich. Composition: Ordinary flaxseed. Fraudulently represented as a relief for habitual constipation and a cure for catarrh, dysentery and other inflammatory disorders of mucous membranes of lungs, intestines and urinary tract.—[N. J. 29793; March 1939.]

San-Tox Nurse Ground Catnip Herb.—De Pree Co., Holland, Mich. Composition: Common catnip. Fraudulently represented as a cure for colic in children and as an emmenagogue.—[N. J. 29793; March 1939.]

San-Tox Nurse Brand Pennyroyal.—De Pree Co., Holland, Mich. Composition: Chiefly leaf fragments, seeds and seed pods of pennyroyal, contaminated with a large amount of rodent excreta. Adulterated because not composed of dried leaves and flowering tops of pennyroyal and misbranded because the term "Pennyroyal" was false and misleading.—[N. J. 29793; March 1939.]

San-Tox Nurse Brand Sage Leaves.—De Pree Co., Holland, Mich. Composition: Common sage leaves. Fraudulently represented as a tonic and as an aid in the treatment of malaria, excessive sweats and rheumatic fevers.—[N. J. 29793; March 1939.]

[San-Tox] **Nurse Brand Sarsaparilla Compound.**—De Pree Co., Holland, Mich. Composition: Essentially potassium iodide, extracts of plant drugs (including a laxative), alcohol, sugar and water. Fraudulently represented as a blood purifier.—[N. J. 29793; March 1939.]

San-Tox Stomach Bitters.—De Pree Co., Holland, Mich. Composition: Essentially extracts of plant drugs (including an alkaloid-bearing drug), sugar and water. Fraudulently represented to increase the number of white blood cells, correct loss of appetite, incomplete digestion, dyspepsia, etc.—[N. J. 29793; March 1939.]

Soap Lake Salts.—Soap Lake Products Corp., Seattle. Composition: Essentially common salt, washing soda, Glauber's salt and a small amount of potassium chloride. Representations as to its efficacy in treating rheumatism, eczema, pyorrhea, gangrene, etc., were declared fraudulent.—[N. J. 29755; March 1939.]

Vitatonie.—Edward Hidden, New York. Composition: Essentially extracts of plant drugs including nux vomica and a laxative drug, alcohol (34.4 per cent by volume) and water. Fraudulently represented as a "body builder" and a remedy for kidney, liver and stomach disorders.—[N. J. 29764; March 1939.]

ROBINSON'S PERNICIOUS ANEMIA CURE

The Mails Are Closed to a Dangerous Fraud

More than fourteen years ago the Bureau of Investigation looked into a dangerous fake exploited by one W. A. Robinson, of Sisseton, S. D. Following the investigation the facts were given to the medical profession and the public through an article published in this department of THE JOURNAL and later reproduced in a condensed form in "Nostrums and Quackery and Pseudo-Medicine," Volume III, published by the American Medical Association. The condensed report from the book follows:

Robinson's Pernicious Anemia Cure.—From Sisseton, S. D., one W. A. Robinson exploited an alleged cure for pernicious anemia. Original letters written by Robinson indicated that he was a man without any general education and was obviously ignorant of medicine. Robinson's story was to the effect that in 1919 he had what the physicians had diagnosed as pernicious anemia and was told that it was unlikely that he would get well. He then set about it to find a cure for his condition and this he claimed to have done. Robinson's theory of the etiology of pernicious anemia was not new; it was to the effect that the condition is caused by intestinal parasites. He called these parasites "Anemias" and declared that pernicious anemia "is not a disease at all, any more than 'cooties' is a disease." Robinson claimed that he kept up his "research" on the cause and cure of pernicious anemia for nearly seven months (!) and then found both the cause and the cure; that he cured himself and two friends before he began putting the thing on the market. Robinson charged \$30 for his treatment, which he claimed would entirely remove the cause of pernicious anemia in twenty-five days. The treatment consisted of two parts; one was coarse, sharp sand and the other was sometimes a green colored liquid and sometimes some "liver pills." One patient suffering from pernicious anemia took Robinson's nostrum and the sand caused hemorrhages, resulting in the patient's death. Another victim also died following the use of Robinson's treatment and his physician wrote that the end was hastened by the gastric disturbances induced by the treatment.—(Condensed from The Journal A. M. A., Oct. 24, 1925.)

The original article was published in THE JOURNAL Oct. 24, 1925. In 1928 the Post Office Department called on Robinson to show cause why a fraud order should not be issued against

PERSONAL

PERNICIOUS ANEMIA

need no longer be a FATAL disease. After 7 months research every day I found the CAUSE and CURE. I can positively remove the cause in 10 days. If the cause is removed they can get well. If not removed, NEVER. W. A. ROBINSON, SISSETON, S. D.

One of Robinson's old advertisements.

him. In order to escape having the mails closed to him, Robinson on June 14, 1928, executed and filed with the Post Office Department in Washington an affidavit in which he swore that he had "absolutely discontinued" his business of selling an alleged cure for pernicious anemia and he promised that the business would "not be resumed at any time in the future." But in 1936 Robinson was again advertising his "cure." The Post Office Department once more intervened and finally on March 22, 1939, a fraud order was issued against W. A. Robinson, of Sisseton, S. D., closing the mails both to the fraud and to the quack who had conducted it.

Correspondence

INTESTINAL OBSTRUCTION AFTER COLLOIDAL ALUMINUM HYDROXIDE

To the Editor:—In THE JOURNAL October 21, page 1564, appears the report of a case of intestinal obstruction supposedly caused by colloidal aluminum hydroxide. There is much additional information to be desired to that contained in this report. First, what was the diet of the patient while she was receiving the continuous intragastric drip of aluminum hydroxide? From the author's description the material found to be obstructing the small bowel would seem as likely to have been composed of milk curds as anything else. If the patient was largely on a milk diet and the milk was unmodified by the addition of lactose and sodium citrate the formation of curds could be expected. Secondly, if it was to be proved that the aluminum hydroxide caused the obstruction why not present a chemical analysis of the obstructing material? These are two points which need further elucidation by the author.

It has been my practice in a not inconsiderable number of cases of ulcer, with and without hemorrhage, to use a more dilute solution of aluminum hydroxide, mixing three parts of water with one part of the drug and giving it at the rate of 1,500 cc. every twenty-four hours, at the same time allowing a rather liberal soft diet.

The constipating effect of aluminum hydroxide has not been shrouded, as the author contends. In sixty-seven recorded cases and many unrecorded cases in which I have used this preparation I have yet to see constipation develop which is not readily alleviated by the proper use of liquid petrolatum.

CLEMENT R. JONES JR., M.D., Pittsburgh.

To the Editor:—The report by Dr. W. Paul Havens, in THE JOURNAL October 21, page 1564, of an alleged case of intestinal obstruction caused by colloidal aluminum hydroxide deserves some comment, since the use of this antacid either by mouth or by intragastric drip has become quite extensive.

In the case reported, sickness followed severe hemorrhage and 8 cc. of colloidal aluminum hydroxide was administered every two hours for three and a half days, followed by the constant drip of 2,000 cc. of a 1:2 dilution every twenty-four hours. Liquid petrolatum was used only once, but morphine sulfate 10 mg. was administered every four hours for several days. The specific effect of morphine is to contract sphincters, in this way producing a marked degree of constipation.

The evidence of an actual obstruction of the bowel, however, is not convincing. There was no vomiting and apparently only a moderate degree of gaseous distention of the bowel proximal to the lower third of the ileum. The rectum was reported to be full at autopsy after effective enemas. Obviously the intestinal contents were moving downward. It is a question whether the same conditions would not have been found at autopsy in any case in which morphine had been given over a period of days after the ingestion of any other material including bulky food residue.

An opiate should not be used in connection with the aluminum hydroxide drip treatment except in the occasional case in which there is an atypical reaction of diarrhea. For all others, phenobarbital and novatropine or other sedatives are used liberally and liquid petrolatum in one-half ounce (15 cc.) quantities two or three times a day. With these precautions in a series of 407 cases (101 presenting massive hemorrhage) there has been no instance of intestinal obstruction. In the earlier cases there were many instances of an accidental inflow of a whole flask of the aluminum suspension in a short time owing to an air leak in the siphonage system. There usually was no disturbance of the bowel and never as much difficulty in the elimination of

this excess as in some cases of barium retention after x-ray examination. In some cases there will be firm scybala palpable in the left iliac fossa, but with a more liberal use of liquid petrolatum by mouth, an occasional oil enema and the avoidance of opiates impactions are prevented.

If one is familiar with the mildly constipating character of aluminum hydroxide and takes the necessary precautions, especially with the drip treatment, there should be no serious difficulty with the matter of constipation or danger of true mechanical obstruction of the bowel. The astringent properties of aluminum hydroxide seem to have certain advantages in the treatment of ulcer, and many patients testify that symptomatic relief is more complete than with magnesium trisilicate, which is sometimes substituted. The combination of the two non-alkalizing antacids is often useful in ambulatory management.

If the whole principle of antacid therapy is sound, certainly the principle of continuous night and day neutralization is sound. X-ray and other evidence indicates that healing may be obtained in as short a period as ten days and in a higher percentage of cases than can be obtained by the older medical managements over a period of three weeks or more. Hence the importance of getting the exact facts about minor difficulties and the technic to avoid them.

"EXPERIMENTAL CHEMOTHERAPY WITH SULFANILAMIDE AND RELATED COMPOUNDS"

[An addendum to paper in THE JOURNAL November 4].

To the Editor:—An exception to the specificity of the reaction for the detection of oxidation products of aromatic amines (described in *Public Health Reports* 54:1880 [Oct. 20] 1939) has been found in that positive results were obtained with the glucosides of sulfanilamide and 4,4'-diaminodiphenyl sulfone. Apparently this linkage protects the amino group from acetylation, but the glucoside is later split off by the nitrous acid employed in diazotization.

Observations made with the original technic must be interpreted in the light of these observations. Our results on urinary excretion of a hydroxylamine derivative following administration of sulfanilamide must be reexamined to determine to what extent other derivatives were involved in the reaction.

Attempts are being made to modify the procedure so that these difficulties will be overcome.

SANFORD M. ROSENTHAL, M.D., Washington, D. C.
Senior Pharmacologist, U. S. Public Health Service.

ELECTROCARDIOGRAMS

To the Editor:—In the August 12 issue of THE JOURNAL, Drs. Strouse, Katz and Binswanger discussed a feature of electrocardiographic study which is worthy of reemphasis. Textbooks and the literature have not sufficiently stressed the problem and the significance of basic and serial electrocardiograms. By careful study of patients and graphs one finds that the single picture is usually of no clinical value except as it presents definite diagnostic features. Especially is this true in coronary disease on an arteriosclerotic basis, in which progression of the pathologic condition may take place without clinical exhibition of variation in cardiac disorders or even in symptomatology.

It seems that the best way to detect lesions early is by taking the patient's cardiac "fingerprints" and follow these up subsequently; i. e., a routine electrocardiogram of all patients over the age of 40 at the time of a general physical examination. Later follow-ups will help in early diagnosis of the presence or extension of disease by comparative study. It is in coronary

disease that this procedure will have inestimable value and possibly help in preventing early or avoidable cardiac morbidity.

Here is an example of the importance of an early presymptomatic electrocardiogram. It is known that the T wave may be normally inverted in lead 3. But it is not known what the normal is for any individual unless one has his cardiac "finger-prints." A man of 62 with no symptoms had a normal electrocardiogram in the four leads with inverted T₃, which is not considered pathologic. Four months later the first manifestation of posterior infarction was pain in the back, but the electrocardiogram showed an erect T₃, which had been inverted. This was interpreted as a coronary disorder and within two days a typical graph of occlusion was evident. If the "normal" electrocardiogram had not been available, a case of this sort might have been overlooked.

The electrocardiogram, when properly used and interpreted, is an extremely useful adjunct to the history and examination in arriving at a definite diagnosis and prognosis in some cases in which doubt would prevail regarding the management of the case.

Since heart disease has assumed the position of Osler's "Captain of the Men of Death," I feel that this plea for early and serial electrocardiograms should seriously be considered by all doing cardiac work.

SAMUEL WALDMAN, M.D., Brooklyn.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ANGINA PECTORIS, NEUROCIRCULATORY ASTHENIA AND MENOPAUSE

To the Editor:—Two years ago a married Jewish woman 51 years old developed an anginal syndrome parallel with her menopausal syndrome. Only since two months ago has definite evidence of coronary sclerosis been identified by electrocardiograph. She has never had decompensation, but lately some cyanosis of the lips and finger nails has been visible and paroxysmal tachycardia has developed. Since the prognosis is apparently poor and since it is felt that her years are numbered, I wish you could tell me whether the injection of alcohol into the sympathetic and parasympathetic ganglions and nerves of those leading to the heart is rational therapy and what neurosurgeons are capable of performing these injections. Glyceril trinitrate and other vasodilators have been used without success. What other types of therapy may safely be used on this form of heart disease?

Jacob C. Dorfman, M.D., Rochester, N.Y.

ANSWER:—It is most important in the first place to be absolutely certain of the diagnosis of angina pectoris in this patient with the menopause. She is probably in a highly nervous state and one must carefully rule out neurocirculatory asthenia, which will be associated frequently with heartache and anterior chest pain. The very failure of her discomfort to be relieved by glyceryl trinitrate is strong evidence against angina pectoris.

The electrocardiographic evidence of coronary disease does not prove the presence of angina pectoris. She might have either one alone, and many persons with neurocirculatory asthenia have also electrocardiographic evidence of coronary disease without any angina pectoris. There are in this case some evidences of irritability of the heart and circulation not necessarily in keeping with coronary disease, for example cyanosis of the lips and finger nails and paroxysmal tachycardia.

If, however, the most careful consideration indicates the presence of an important and, to a certain extent, a crippling degree of real angina pectoris, radical therapy should be considered. However, it is best to try to postpone it until after the menopause is completed because the clearing of the menopause itself may result in definite improvement and moreover there are many instances of spontaneous recovery from coronary insufficiency. This has been found to be almost the rule. Coronary disease may continue, of course, but the development of collateral coronary circulation renders the state of health much better.

Paravertebral injection of alcohol is, although helpful, to be considered a radical measure and to be postponed until all adequate medical measures, including nitrites, have proved unavailing. It is well to wait a year or two or more before undertaking any radical methods of treatment unless the situation is really bad.

MYOTONIA ACQUISITA

To the Editor:—A patient for whom I have made a diagnosis of myotonia acquisita rather than myotonia congenita shows generalized rigidity with a tendency to corugation of muscles when they are stimulated. He shows no symptoms which would lead to the diagnosis of tetany. In line with the recommendations in the literature, he has been receiving quinine sulfate by mouth, beginning at 15 grains (1 Gm.) daily and increasing to as high as 30 grains daily. He has also received calcium intravenously, and on several occasions he stated that he "loosened up" for some time after the injection. However, now he does not seem to have a favorable response from the treatment I am giving him. Can you suggest any other form of therapy which might prove helpful?

George B. Fletcher, M.D., Hot Springs National Park, Ark.

ANSWER:—Not enough of the patient's symptoms are given for one to be sure that the diagnosis of myotonia acquisita is correct. One would want to know the patient's age, his previous history with regard to neuritis and whether the condition was familial or hereditary. One fact, however, probably points to a diagnosis of myotonia acquisita. The patient has been receiving quinine in adequate dosage without favorable response. This in itself indicates that the disease is of the acquired type rather than myotonia congenita. Alexander Wolf (*An Effective Form of Treatment for Myotonia, Arch. Neurol. & Psychiat.* 36:382 [Aug.] 1936) and other investigators have shown conclusively, and it has been observed by others, that patients with myotonia congenita respond quickly to quinine. It is possible, therefore, that the lack of response by this patient is helpful in making the diagnosis. A favorable response to quinine is not to be expected in the acquired form of myotonia.

It is felt by most investigators at the present time that myotonia acquisita is not a familial or hereditary disease. It may follow neuritis of a mild type, and the hypertrophy of the muscles found in this condition is indistinguishable from that found after neuritis. The condition usually occurs in early adult life, often is mild and may go on to complete recovery. The disease is rare and only a few cases have been reported in the literature. Myotonia congenita, however, is more common, although it too is rare. If there is any evidence of neuritis, such as tenderness along the course of the nerves, lost reflexes, vasomotor or trophic changes, or alterations in the electrical responses, treatment should be directed toward the neuritis itself.

Any specific treatment for myotonia acquisita is not known. Knud H. Krabbe (*Myotonia Acquisita in Relation to Post-neuritic Muscular Hypertrophies, Brain* 57:184 [June] 1934) simply stated that his patient "was given thyroid extract and improved considerably; power and rate of movement increased and the muscles seemed to diminish in bulk." If, as Krabbe suggests, the condition is due to "excessive" recovery from the polynneuritis, thiamin chloride appears not to be indicated. The response in patients with the atrophic form of myotonia to amphetamine sulfate is encouraging. From 5 to 20 mg. a day may be given, in two or four doses. Although no reports of its use in myotonia acquisita are at hand, it is worthy of trial. It must not be forgotten, however, that spontaneous recovery from myotonia acquisita is not unknown. Sources of infection in the body which might give rise to polynneuritis are to be sought for. Mild gymnastics are advocated and a warm climate is said to be beneficial.

FETOR ORIS

To the Editor:—Please discuss causes, physical and chemical, of feter oris arising from the oral cavity.

M.D., Massachusetts.

ANSWER:—Feter oris originating in the oral cavity may be divided into three types, arising from (1) retained food particles or their decomposition products, (2) decomposition of oral tissues or fluids and (3) volatile substances absorbed elsewhere in the body and released from oral tissues or fluids secreted into the oral cavity. By the use of a method described by Brening, Sulser and Fosdick it is possible to gain some idea of both the intensity of the odors and their source with respect to the part played by the lungs, nasal cavity and oral cavity.

There appears to be disagreement among investigators with respect to the importance of the role which food particles play. Some believe that they are relatively insignificant; others offer evidence that such substances as onion and garlic chewed but not swallowed may be detected from sixty to seventy-two hours after mastication. The period is appreciably longer than when

the same substances are ingested by capsule. The physical opportunities for lodgment and decomposition of food debris offered by the embrasures between the teeth, cavities produced by caries or other mechanical factors. Oral chemical reactions occurring in degenerative and suppurative lesions in the mouth such as pyorrhea are unquestionably of importance. Some believe that the stagnation of oral fluids and desquamation of epithelium of the mucosa may give rise to unpleasant odors. The lesions of dental caries affecting only the calcified tissues of the teeth are less significant, but the opportunities which they offer for the lodgment of food allow putrefactive changes, and their extension to the point of exposure of the dental pulp may initiate degenerative changes in that organ which can unquestionably contribute to fetor oris.

In addition to these regional causes there is considerable evidence indicating that the oral secretions may give up volatile substances which were assimilated by the blood and other tissue fluids from the gastrointestinal tract, the lungs or other organs. The existence of this systemic factor has been proved experimentally but its relative importance when evaluated with respect to the regional factors is still debatable. All must be carefully investigated when searching for a cause in a specific instance. The following references together with their bibliographies may prove of value to any one interested in pursuing the subject:

POSITIONAL CHANGE OF FETUS IN UTERO

To the Editor:—Can you give me some idea as to what might be found in the literature concerning change of position and presentation of the fetus during the last month of pregnancy? On two occasions in the antepartum clinic I have seen the diagnosis of the presentation reversed at delivery within a week of the last examination. When I talked to several physicians concerning this, opinion was varied. Most had had a similar experience, but many felt that they had been incorrect in their original diagnosis. A few were certain that their diagnosis had been correct and that the fetus had changed position. On Aug. 3, 1939, in our antepartum clinic we examined for the first time a 44 year old primigravida. In the attempt to ascertain the position of the fetus, neither the external nor the pelvic examination was entirely satisfactory. This was due to the fact that the patient was large and obese (250 pounds [113 Kg.]). Further examination disclosed a blood pressure of 180 systolic and 110 diastolic, edematous ankles and moderate anemia. A roentgenogram taken at this time showed the fetus in a transverse position with the head to the right. The fetus appeared to be near full term and according to the menstrual history delivery was due about August 25. We decided it would be best to hospitalize the patient, attempt to control her eclampsia, build up her blood and seek consultation as to the feasibility of performing a cesarean section. The consultant advised complete bed rest, restricted fluids, salt-free diet, iron and liver and an x-ray check-up in a week. After one week of this regimen the ankle edema disappeared, the blood pressure went down to 150/90, and the red count and hemoglobin improved. The roentgenogram taken at this time (August 11) showed a breech presentation with the sacrum to the right. In view of this observation it was decided to make pelvimetric determinations by means of roentgen precision stereoscopy. The next day (August 12) this showed a vertex presentation, with the occiput to the right anteriorly. There was no disproportion. On September 6 the patient went into labor and a roentgenogram taken at this time showed the presentation to be vertex with the occiput to the left. The patient was delivered of a living boy with low forceps. This series of roentgenograms, particularly the two taken in twenty-four hours which showed a change from breech to vertex presentation, was especially interesting, more so because this had taken place while the patient was at complete bed rest and there had been no attempted external manipulation. Can you tell me whether or not a change in presentation of a fetus over a twenty-four hour period is recognized as a fairly common occurrence and whether there has been any work done in this line and verified by x-rays?

Nicholas P. Dallis, M.D., Glen Cove, N.Y.

ANSWER.—Presentation and position are the result of a process of accommodation of the fetus to the uterus and the pelvis. Many factors may influence normal accommodation in the uterus during the last part of pregnancy and result in varying presentations and positions. An excessive amount of liquor amnii, relaxation of the abdominal wall, an unusually large pelvis, abnormalities of the fetus and abnormalities of the uterus are some of these factors. Normally when the presenting part becomes engaged in the inlet of the pelvis no change in presentation can occur. In the primipara engagement usually takes place during the last month of the pregnancy. However, when this does not occur a change of polarity and of position of the presenting part can easily take place. During the seventh and eighth months of gestation many babies present by the breech. These breech presentations most often change into cephalic before engage-

ment takes place. Many observers have noted a change in polarity within a period of hours or days.

The patient in question undoubtedly had a large pelvis, which may have been a factor in the change in polarity and position of the fetus. Undoubtedly, such changes in presentation and position occur commonly without the knowledge of physicians. No report of careful study of this problem by means of frequent roentgenograms has been found.

EOSINOPHILS IN RHINITIS—DEGREE OF SUFFERING IN HAY FEVER

To the Editor:—1. In a case of rhinitis of questionable etiology does the presence or absence of large numbers of eosinophils in the nasal secretions indicate or exclude hypersensitivity as the cause? 2. Two patients have received prophylactic treatment by the perennial method for dwarf and giant ragweed hay fever for the past three years. Prior to the onset of the fall hay fever season both received up to 10,000 pollen units of mixed extract. They were remarkably free of symptoms during the first two years but have suffered rather severely during the present season. Intervals of injection and dosage have been identical each year. What can be the explanation for this phenomenon? M.D., New York.

ANSWER.—1. The presence of a large number of eosinophils in the nasal smear is definite proof that the rhinitis is of an allergic nature. If only a few eosinophils are present the diagnosis becomes somewhat doubtful and must then be deduced from the history, the presence of some other allergic conditions in the patient or of allergy in the family and from cutaneous tests. The absence of eosinophils does not exclude allergy. If a patient with allergic rhinitis develops an ordinary infectious coryza, the nasal smear will usually show a temporary diminution or absence of eosinophils and a predominance of polymorphonuclear cells.

2. There are four possible explanations for the increased suffering. First, the ragweed hay fever season this year, in certain parts of the country, at least, has been much more severe than in any previous year since 1935. For example, in the Middle West the amount of ragweed pollen has been from 50 to 75 per cent greater than in 1938. Second, the material used for injections may not have been up to standard; perhaps it had deteriorated. New extracts should be used every year and some physicians prefer to change their solutions every few months. Third, the two patients may possibly belong to the small group whose symptoms seem to become aggravated more and more as they receive injections. Fortunately, the large majority seem to improve year after year under treatment. Fourth, some physicians believe that pollen varies in toxicity from year to year. This is difficult to prove, but from the large amount of hay fever suffering this season, it might well be a factor.

HERRMANN MEASUREMENTS OF HEART AND MALINER'S TEST

To the Editor:—Will you please evaluate, explain and give me some information on (1) Herrmann measurements of the heart and (2) Maliner's test. If the Herrmann measurements showed an enlargement of the heart but the cardiothoracic ratio was normal and there was no clinical evidence of any heart condition, would you not believe that the cardiothoracic ratio was probably the correct determination? M.D., Illinois.

ANSWER.—Herrmann's measurements of the heart consist of comparison of the weight of the left ventricle with the weight of the right ventricle by a special method of dissection different somewhat from that carried out by Lewis, in which the heart was dissected away in toto. Herrmann's method has been described in the *American Heart Journal* (1:213 [Dec.] 1925). The ratio which he found in the dog's heart, L/R (ratio of left ventricle to right ventricle), was 1.393 with a minimum of 1.153 and a maximum of 1.773. By Lewis's method this ratio averaged 1.461 with a minimum of 1.450 and a maximum of 1.880. Maliner's test, as reported by M. M. Maliner and W. F. Matthews (*Arch. Pediat.* 56:142 [March] 1939), is a modification of Master's two step exercise test. Maliner and Matthews studied a group of 200 children and twenty-five noncardiac clinical patients and came to the conclusion that the measure of exercise tolerance as determined by this two step test is fairly constant but that changes in the pulse rate are less important than variations in the systolic blood pressure. This exercise tolerance test was presented originally by A. M. Master and E. T. Oppenheimer (*Am. J. M. Sc.* 177:223 [Feb.] 1929) and was further discussed by Master (*Am. Heart J.* 10:495 [April] 1935). The roentgenographic cardiothoracic ratio may be normal with no clinical evidence of heart disease and yet the actual size of the heart, especially the ratio of right to left ventricle, may be greater than normal.

SUBACUTE GONORRHEA AND SULFAPYRIDINE

To the Editor:—A man aged 31 had intercourse on August 2 and first noticed a discharge on August 11. He came in for treatment at once and was started on sulfanilamide 80 grains (5 Gm.) daily for five days. The discharge became less for two days and then again became profuse. The dose of sulfanilamide was increased to 120 grains (8 Gm.) daily, and the discharge disappeared in three days. Examination of the prostate and seminal vesicles at that time showed no signs of involvement. A prostatic smear, however, was strongly positive for the gonococcus. The sulfanilamide was reduced to 80 grains daily, and the discharge promptly reappeared. Hand injection with mild protein silver 5 per cent was begun at this time. After a week of this treatment, the sulfanilamide was reduced to 45 grains (3 Gm.) daily. This dosage was maintained until September 6. While there was a decrease in the amount of discharge at that time, there was always some present. With the hope that the organisms would lose their apparent tolerance to the drug, the sulfanilamide was then discontinued for ten days, and irrigations of 1:5,000 acriflavine were given in the office every other day. The hand injections of 5 per cent mild protein silver were continued by the patient at the same time. The sulfanilamide was again given in a dosage of 120 grains daily for three days, then dropped to 80 grains daily. The discharge, while less in quantity, has still persisted and may be obtained at almost any time. The smear is still positive for gonococci, although considerable searching is necessary to find them. It seems to me that this patient has had more than sufficient treatment. Would you suggest that the treatment be continued or changed? What treatment do you believe advisable? What is M. & B. 693, and where can it be obtained? Some of the British literature seems to favor this drug over sulfanilamide.

M.D., Iowa.

ANSWER.—From the history given, this is a case of subacute gonorrhea probably with some involvement of the posterior urethra. Before instituting further treatment it would be advisable to do complete blood counts, including differential, since the large doses of sulfanilamide which have been given are apt to produce anemia or other blood dyscrasias. Complete physical examination is also indicated, with special attention to the peripheral nerves. With negative results from these tests it would be safe to institute therapy with sulfapyridine, which is M. & B. 693 and is sold by several leading drug houses. In this case the dose should be 60 grains (4 Gm.) the first day, 40 grains (2.6 Gm.) the second and third days and 30 grains (2 Gm.) for four more days. Local treatment in the form of hand injections of 5 per cent mild protein silver twice a day should be continued, but no more than 4 cc. should be injected and this after micturition. At the end of a week urethral and prostatic smears should be studied, and appropriate tests of cure such as passage of a sound followed by instillation of 0.33½ per cent silver nitrate, ingestion of alcohol and intercourse should be tried. If at any time the gonococcus is rediscovered, another course of sulfapyridine should be given exactly as before. This may be necessary because of the chronicity of the involvement and the previous use of large doses of sulfanilamide, which seems to necessitate a larger total dose of sulfapyridine. The effectiveness of sulfapyridine in gonorrhea is estimated to be from two to three times that of sulfanilamide; however, it is always necessary to administer local treatment with either drug.

EFFECT OF SACCHARIN

To the Editor:—What are the deleterious effects of the prolonged use of saccharin? I have a patient who has been using about 10 grains (0.65 Gm.) a day for several years. Occasionally he shows a questionable reaction for albumin in the urine. The patient also has an arrested case of pulmonary tuberculosis. His diabetes is fairly well controlled by diet and insulin.

V. F. Neumann, M.D., Norwich, Conn.

ANSWER.—Blodgett has reported that a patient of his with glycosuria used from 7 to 8 grains (0.45 to 0.52 Gm.) of saccharin daily for twenty-four years with never a symptom that could be attributed to saccharin. He also described several cases in which patients suffering from obesity and treated with diets restricted in carbohydrate had used saccharin daily for fifteen years without deleterious effect. Blodgett considered saccharin a condiment and not a drug. Wilcox studied the therapeutics of saccharin and concluded that it may be used indefinitely in amounts tolerable to taste without harm. Although Sollmann stated that it is harmless and that from 70 to 90 per cent is excreted unchanged in the urine, cases of saccharin poisoning have been reported by Grundfest and by Heilmann. However, no albuminuria was found and the doses used were enormous. By far the most complete study on the physiologic actions of saccharin was that made by Carlson and his associates for the Referee Board. They found that a dog with 75 per cent of its total kidney tissue removed by nephrectomy could be given from 5 to 20 Gm. of saccharin daily for six weeks without any effect on kidney function or nitrogen metabolism but that intravenous injection of from 10 to 25 Gm. of saccharin into a dog with only one kidney or into a normal dog resulted in some diminution of kidney function as determined by the phenolsulfonphthalein excretion during the first hour. Carlson and his co-workers pointed out that their short

term feeding experiments did not exclude the possibility of injurious effects of smaller amounts of saccharin taken over a long period, particularly by persons in the older age groups.

It appears from this evidence that the possibility in the case cited of 0.65 Gm. of saccharin causing albuminuria is remote. While final proof of the matter would require demonstrating that increasing the intake of saccharin caused increased albuminuria and vice versa, the more common causes of traces of albuminuria should be investigated before placing the blame on saccharin.

ABORTION AND MENSTRUAL FLOW

To the Editor:—A healthy married woman aged 37, mother of two healthy children aged 9 and 5, has the following history: On May 26, 1939, she had her usual normal and regular menstrual period of the twenty-eight day type with five days' duration. On or about June 7 she became pregnant. On July 17 she was hospitalized for spontaneous threatened abortion. On July 22 the abortion was considered inevitable and the uterus was emptied by ovum forceps and curet. On July 29 she was discharged from the hospital after an uneventful postoperative course. On August 5 she was with her husband for the first time after the operation. On August 12 she started flowing at what she considered the right time had she not become pregnant. After the flow had continued for one week it was regarded by the family physician as functional bleeding, and during the second week of the flow antuitrin-S in the amount of 600 units was given in divided doses. During this second week of flow an occasional stringlike clot was passed but there was no pain. At the beginning of the third week of bleeding progesterone was given on two consecutive days in 1 unit doses. On the day of the second dose there were crampy pains in the pelvis and back, and a clot the size of a hickory nut was passed but not seen by the physician. On the third day of the third week of flowing the patient was examined by an obstetrician, who said the uterus was slightly enlarged and the os half the size of a finger. He advised a uterine stimulant and in three days the flow stopped and there has been no further show. 1. How soon after a fruitful coitus might an abortion occur? 2. If this was not an abortion, what might it have been?

M.D., Iowa.

ANSWER.—The involution of the uterus is relatively longer after an early abortion than after a term pregnancy. The woman in question was discharged from the hospital seven days after the uterus was emptied and had intercourse fourteen days after the abortion. Two reasons may be given for the uterine bleeding. Probably the real one is that it was a normal menstrual function, but it might have been from subinvolution of the uterus. Normal menstruation is frequently disturbed for a time following abortions and term pregnancies and usually calls for no treatment. It is difficult to see the reason for the treatment given, certainly as given at that time. Rest in bed, a few hot vaginal douches and ergot would seem to have been more logical. It is common for a multiparous woman to have a slightly enlarged uterus at the period examined. It is possible for an abortion to occur within a few days after a fruitful coitus. The age at which the ovum is embedded in the uterus is not settled but is probably not over eight days. De Lee says that an expelled ovum the size of a pigeon's egg is approximately 4 weeks of age, and one the size of a hen's egg from 6 to 7 weeks.

TUBERCULOUS EMPYEMA AND OLEOTHORAX

To the Editor:—Is there any solution that can be used effectively in cleaning up tuberculous empyema?

M.D., Chicago.

ANSWER.—There is no solution which is effective in cleaning up tuberculous empyema. Oleothorax, however, gives satisfactory results to the extent of from 60 to 70 per cent of the cases in which it is used. To replace the exudate, which is generally removed by aspiration at regular intervals, plain sterilized olive oil without medication is injected into the plural space. Irrigation with physiologic solution of sodium chloride or with diluted solution of sodium hypochlorite, if preferred, is done with a syringe having a large caliber needle. There is absolute bed rest during the course of treatment.

To guard against any untoward reactions, the first injections of oil are in small amounts, 5, 10 or 20 cc.; then more oil may be added fractionally until the space is filled or the desired indication is reached. In some cases, when the exudate persists, aspirations can be done below the oil level without removing the oil and the amount aspirated replaced with the oil.

This form of treatment has given excellent results in a large number of cases, and no ill effects result from the olive oil. When, however, the pathologic process in the lung beneath the purulent exudate is more advanced, as with secondary infection of the tuberculous empyema, cavitation, bronchopleural fistula or pleurocutaneous fistula, a thoracoplasty may have to be resorted to.

IRREGULAR MENSES AND OBESITY AT MENARCHE

To the Editor:—A girl aged 14 weighing 160 pounds (73 Kg.) is normal to physical examination except for being overweight. Urine and blood tests are normal. Her first menstrual period began Feb. 1, 1939, and was profuse for a week. I gave a preparation of iron to prevent any anemia and stated that menstruation would adjust itself, in all probability. The flow continued, however, and on February 10 her red cell count was 4,500,000. Owing to the general appearance of obesity I gave her thyroid extract, one-half grain (0.03 Gm.) twice a day, and antuitrin-S every other day for six or eight doses. The flow continued until February 23, at which time a curettage was done. The uterus and genital tract were apparently normal. The laboratory report showed the material from the uterus to be normal. While in the hospital, she was under the care of a gynecologist and was given antimenorrhagic factor tablets three times a day. Since then she has menstruated fairly regularly two or three times, but now her periods are getting closer together. The last was at an interval of two weeks. Treatment has consisted of thyroid extract, one-half grain twice daily given continuously, and antimenorrhagic factor, three times a day a week before each menstrual period. Between periods she has had a tiny amount of discharge which has been unrevealing. The parents are rather anxious as to her irregularity. Physically she is in good health. Would progesterone or gonadotropic substance or another of the glandular preparations be beneficial? M.D., Indiana.

ANSWER:—There is no need to give this child any treatment for her menstrual irregularities at the present time. Undoubtedly the same results would have been obtained without the curettage, which is rarely indicated at puberty. Since the patient is definitely overweight, she should be placed on a diet which will make her lose weight. This may be accomplished without thyroid therapy but in this case the small amounts of thyroid may be helpful. Irregularity of the menses is frequent at onset and may last a year or more. As long as the amount of blood is not excessive and the patient does not become anemic, no special treatment is needed.

CEREBELLAR ATAXIAS

To the Editor:—A patient with cerebellar ataxia has a brother who is worried about also having it because it is hereditary. This brother heard that glandular therapy is preventive treatment. If there is any glandular therapy or other treatment for cerebellar ataxia that is preventive, will you please advise me. M.D., Illinois.

ANSWER:—There is no known prophylactic (preventive) or active treatment of any of the cerebellar ataxias that are hereditary, familial or both. The ages of the patient and his brother are not mentioned. If the patient is adolescent, he probably has spinal cerebellar ataxia of Friedreich or hereditary cerebellar ataxia of Marie. If he is older (between 30 and 50) he may have the form known as primary progressive cerebellar degeneration of Holmes. All these varieties are due to a defective anlage in the cerebellar structures and there is no treatment.

TRANSMISSIBILITY OF TRACHOMA

To the Editor:—A man aged 54 has had trachoma for ten years. Recently he began supplying a community with raw milk. Should he be allowed to milk, bottle milk or work about the barn or milk house in any capacity? George S. Enfield, M.D., Bedford, Pa.

ANSWER:—It is necessary to bear in mind that (1) trachoma is not communicable to domestic animals; (2) the infection is disseminated by direct or indirect contact from eye to eye only, never by intestinal or other ports of entry; (3) in general, the dosage for implantation must be repeated or relatively massive; (4) the infectious agent or virus is rapidly inactivated by dilution or when once removed from its normal habitat, and (5) the contagiousness of a given patient decreases with duration of the disease, so that with the possible exception of an acute flare-up a case of ten years' standing would only rarely serve as a source of infection. In this particular instance, therefore, it may be said that, while the idea may offend one's sensibilities and perhaps even oppose more general precepts of public health, the possibility of spreading trachoma under the conditions outlined is extremely remote. Of course pasteurization of milk would eliminate remonstrances from the most conscientious of objectors.

Regarding the matter from the point of view of the patient, it must be remembered that employment about farms, barns and the like maintains a constant exposure to dust, strong variations in light and other factors which promote conditions for exacerbations of trachoma.

MAGNESIUM SULFATE IN CARDIAC ARRHYTHMIAS

To the Editor:—Please outline the rationale for and the technic of the use of magnesium sulfate in paroxysmal tachycardia. In what other forms of heart disease is it indicated?

Alice S. Cutler, M.D., Los Angeles.

ANSWER:—Theoretically and experimentally the magnesium ion is known to depress all muscle and nerve function, and so magnesium sulfate has been suggested for control of disordered heart rhythm, especially premature beats and paroxysmal tachycardia. However, with large enough doses to have such a depressing effect, the toxic action on the myocardium and on the central and peripheral nervous system is of important consideration; experimentally dilatation and standstill of the heart have been produced by magnesium salts. Actually little favorable effect has been found in the use of magnesium in disturbances of heart rhythm. Magnesium sulfate is much more useful in cardiac cases as a mild watery purge in congestive failure. It acts as an osmotic cathartic. Large doses, that is, enough to produce several stools a day, are to be avoided because of the fatigue that ensues. Magnesium is antagonized by calcium.

CORONARY DISEASE AND GOITER

To the Editor:—Is coronary disease more frequent among those who have goiter than among those who do not?

Richard E. Stifel, M.D., Cleveland.

ANSWER:—This is an important question, but a satisfactory answer cannot be given at the present time. What little evidence there is does not support the view that coronary disease is more frequent among those who have goiter. Angina pectoris is rare in patients with toxic goiter and, when it does occur, tends to disappear after a thyroidectomy. In patients with myxedema, angina may first appear during the administration of desiccated thyroid.

THROMBOPLASTIN

To the Editor:—In *The Journal*, July 29, page 381, is given a test for vitamin K deficiency using thromboplastin with directions for preparing the thromboplastin. Is the ordinary thromboplastin of the drug trade satisfactory? If not, where can the type described be purchased?

M.D., Florida.

ANSWER:—It is believed that none of the preparations of thromboplastin now on the market are suitable for use in the prothrombin test described in the article cited. It should probably be possible to market suitable material in dried form in tubes of a size appropriate for the test. With the directions given in the article mentioned, any one can prepare the material from fresh tissue at relatively slight expense.

NO ELECTRICAL STIMULATION EFFECTIVE FOR PREMATURE EJACULATION

To the Editor:—What apparatus can produce sinusoidal-foradic current of moderate rapidity used in the treatment of ejaculatio praecox to tone the weak and relaxed muscles of the penis? M.D., Philippine Islands.

ANSWER:—No electrical stimulation of muscle will tone weak muscles. With regard to erection of the penis and ejaculation, Wiggers states: "Before coitus can take place the male copulatory organ must become hard and erect. The increased rigidity is due to flooding of the cavernous spaces with blood as a result of dilatation of their afferent arterioles. Compression of external veins by skeletal muscle contraction does not occur. Secondly, the venous outflow from the efferent veins may be impeded, however, owing to compression from within against the rigid outer coat. Erection, which occurs coincidentally, is not due to muscular action but is produced through a mechanical leverage action of the suspensory ligaments attached to the posterior portion of the cavernous tissue."

CHAULMOOGRA OIL IN TUBERCULOSIS

To the Editor:—I have read with interest your note in the *Journal*, October 7, page 1432, on chaulmoogra oil in tuberculosis, in which you say "Unfortunately, there is no proof available that chaulmoogra oil has any beneficial effect in the treatment of tuberculosis in any form." I have been interested in this subject and, in going over the references that you cite, notice that one of the most recent reports on this subject is not included. I refer you to an article by Dr. J. Edgar Wallace (*Brit. M. J.* 1:1151 [June 5] 1937) in which he reports encouraging results following the intradermal injection of esters of hydnocarpus oil in lupus vulgaris, as follows: "The intradermal injection of hydnocarpus oil in the small number of cases so far available, has produced extremely encouraging results, and appears to offer certain advantages over other routine methods." I am bringing this to your attention because this reference is more recent than any that you cite.

Robert C. Page, M.D., Mount Vernon, N. Y.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, December 2, page 2083.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 5. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: *Basic Science*. Tucson, Dec. 19. Sec., Dr. Robert L. Nugent, University of Arizona, Tucson. *Medical*. Phoenix, Jan. 2. Sec., Dr. J. H. Patterson, 826 Security Building, Phoenix.

ARKANSAS: *Basic Science*. May or June. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, Jan. 17. *Written examination*. Los Angeles, Feb. 26-29. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: *Basic Science*. Denver, Dec. 13-14. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver. *Medical Endorsement*. Denver, Jan. 2. *Medical Examination*. Denver, Jan. 3-5. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 10. Chairman, Dr. Charles M. Bakewell, State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, April 22-23. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

GEORGIA: Atlanta, June. Joint-Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

IDAHO: Boise, April 2. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Jan. 23-25. Acting Superintendent of Registration and Education, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Jan. 9. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KANSAS: Topeka, Dec. 12-13. Sec., Board of Medical Registration and Examination, Dr. J. E. Hassig, 905 N. 7th St., Kansas City.

MARYLAND: *Regular*. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homopathic*. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 12-14. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 2-3. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 16-18. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*. Helena, April 1. *Examination*. Helena, April 2-3. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science*. Omaha, Jan. 9-10. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Reciprocity with oral examination*. Carson City, Feb. 5. Sec., Dr. Frederick M. Anderson, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 14-15. Sec., Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 18-19. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 8-9. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 29-Feb. 1. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: *Reciprocity and Endorsement*. Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: *Basic Science*. Portland, Feb. 24. *Applications must be on file not later than Feb. 7*. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

PUERTO RICO: Santurce, March 5. Sec., Dr. O. Costa Mandry, Box 3834, Santurce.

RHODE ISLAND: Providence, Jan. 4-5. Sec., Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TENNESSEE: Memphis, Dec. 20-21. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WISCONSIN: Madison, Jan. 9-11. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

WYOMING: Cheyenne, Feb. 5. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

District of Columbia Reciprocity Report

Dr. George C. Ruhland, secretary, Commission on Licensure, reports nine physicians licensed by reciprocity on September 28 and October 18. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University School of Medicine.....	(1935)		Georgia
Georgetown University School of Medicine.....	(1927)		Maryland
Howard University College of Medicine.....	(1929)		Ohio,
(1935) North Carolina, (1936, 2) Virginia			
Johns Hopkins University School of Medicine.....	(1937)		Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1935), (1936)		Maryland

Indiana June Examination

Dr. J. W. Bowers, secretary, Indiana State Board of Medical Registration and Examination, reports the written examination held at Indianapolis, June 20-22, 1939. The examination covered fifteen subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Loyola University School of Medicine.....	(1938), (1939)		2
Northwestern University Medical School.....	(1939)*		1
University of Illinois College of Medicine.....	(1939, 2)		2
Indiana University School of Medicine.....	†, (1939, 98)		99
Harvard Medical School.....	(1939, 2)		2
Julius-Maximilians-Universität Medizinische Fakultät, Würzburg.....	(1922)		1
Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn.....	(1937)		1

* License has not been issued.

† This applicant has completed three years' work and will not receive his degree or license until 1940.

Rhode Island October Examination

Dr. Robert M. Lord, secretary, Rhode Island State Board of Examiners in Medicine, reports the oral, written and practical examination held at Providence, Oct. 5-6, 1939. The examination covered twelve subjects and included seventy-five questions. An average of 80 per cent was required to pass. Twelve candidates were examined, all of whom passed. Three physicians were licensed by endorsement. The following schools were represented:

Vermont June Examination

Dr. W. Scott Nay, secretary, Vermont State Board of Medical Registration, reports the written examination held at Burlington, June 14-16, 1939. The examination covered twelve subjects and included ninety questions. Seventeen candidates were examined, all of whom passed. The following schools were represented:

Book Notices

Pneumonia with Special Reference to Pneumococcus Lobar Pneumonia. By Roderick Heffron, M.D., Medical Associate, the Commonwealth Fund. Cloth. Price, \$4.50. Pp. 1,086, with 18 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1939.

The medical profession is indebted to Dr. Heffron for this scholarly volume on pneumonia, published by the Commonwealth Fund at a price permitting wide distribution. It is a well conceived and splendidly executed monograph of permanent value. Our current knowledge of pneumonia in the clinic, in the laboratory and in the community is presented with evident diligence, careful documentation and balanced judgment in twenty chapters dealing with causative organisms in pneumonia and pneumonia not due to pneumococci, the pneumococcus and type incidence in pneumonia, pathology of lobar pneumonia, aspects of immunity, experimental pneumococcal infections and pathogenesis of lobar pneumonia, epidemiology, measures for the prevention of pneumonia, symptoms of lobar pneumonia, physical signs in lobar pneumonia, clinical varieties of pneumonia and association with other conditions, special features in the course of the disease, complications, incidence and treatment, diagnosis, differential diagnosis, prognosis, recovery factors and duration of immunity, general therapeutic measures, serum treatment, results of serum treatment and continuing problems. In spite of the wealth of information presenting our current knowledge of the pneumonias, advances in this field appear so frequently that new editions or supplements may be expected. Sulfapyridine has greatly augmented our capacity to treat the pneumonias and their complications. The whole problem of sulfapyridine fastness has developed since the book went to press. The relative places of sulfapyridine and of serum in therapy are still *sub judice* and the appropriate use for each must be determined. In a comprehensive presentation, the choice of data for inclusion is at times a matter of fine discrimination, which has been well exercised by Dr. Heffron. Nevertheless greater elaboration of the subject of radiographic diagnosis and mention of the significance of lobar segments (described by Kramer and Glass) would have been advantageous. The work of Jacob Fine and others in connection with the treatment of abdominal distention with oxygen is not mentioned nor that of Lamar in connection with the influence of antibody on the lysis of pneumococci. Certain clinical anatomic terms have been saved from oblivion, such as "apical pneumonia," "abortive," "central" and "terminal"; these might well have been "liquidated" in the interest of the etiologic classification, which dominates the volume. The statement that "clinical differentiation of bronchopneumonia from lobar pneumonia is usually not difficult" is not in accord with the experience of many clinicians. The criteria offered for differentiation are not adequate, especially for the infections of children. Of great value is the well selected and inclusive bibliography. The convenience of the excellent index would be enhanced if more synonyms were listed and if there were more cross references. Because it is a thoroughly reliable source book on an important and developing topic of general medical interest and a model of logical presentation, this volume should be on the "must" list of all who provide books for students and practitioners of medicine.

A Descriptive Atlas of Radiographs: An Aid to Modern Clinical Methods. By A. P. Bertwistle, M.B., Ch.B., F.R.C.S. Fourth edition. Cloth. Price, \$15. Pp. 576, with 852 illustrations. St. Louis: C. V. Mosby Company, 1939.

The author seeks to furnish a pictorial reference book of those normal and abnormal conditions which are met more commonly in practice; rare lesions are omitted, except when of special interest. The volume is primarily intended for the use of the clinician, whose chief concern is diagnosis. No special technical knowledge is required in using this atlas. The illustrations, on the whole, are excellent. Some, however, are too small or have lost detail in reproduction and fail to demonstrate the lesion. Most of the roentgenograms are accompanied by diagrammatic sketches, which depict the lesion under consideration. The small size of these outline drawings, the rather crude sketching and the almost illegible microscopic lettering detract greatly from the effectiveness and value of the diagrams.

Standardization of presentation would facilitate the reader's orientation in examining films. For example, the chest films show the heart either on the left or on the right; the stomach and gallbladder pictures are likewise either in the accepted anteroposterior view or in reverse position. Figure 21 and its accompanying diagram are in mirror-image relationship. Fractures are overemphasized in a series of 112 roentgenograms, whereas the vascular system commands only thirteen illustrations; there is no cardiac section. A number of diagnoses are questionable (for example, chronic appendicitis; congenital coxa vara is called Legg-Perthe-Calvé's disease in figure 66; the history and roentgenograms accompanying figures 75 and 76 suggest recovery from paraplegia resulting from cord compression in tuberculous spondylitis rather than spina bifida; the examples of acute osteomyelitis show enough late changes to be considered subacute or chronic. Only a few errors of composition were found. Figure 611 is upside down. Figures 830-834 are grouped without individual identification. The name of Dr. Legg is misspelled "Legge." Despite the foregoing criticisms, the atlas fulfils its purpose to a large degree in providing the general practitioner with a handy reference volume of radiographic interpretation of common lesions.

Sclerosing Therapy: The Injection Treatment of Hernia, Hydrocele, Varicose Veins and Hemorrhoids. Edited by Frank C. Yeomans, M.D., F.A.C.S., M.R.S.M., Professor of Proctology and Attending Surgeon, New York Polyclinic Medical School and Hospital, New York. Cloth. Price, \$6. Pp. 337, with 185 illustrations. Baltimore: William Wood & Company, 1939.

Sclerosing therapy has emerged from the stage of experiment and empiricism. For a long time the domain of itinerant quacks and misunderstood pioneers, it is now taking a definite place in the hands of well trained physicians whose experience is not limited to this form of treatment. It is not the possession of a syringe and needle that qualifies the general practitioner to use such methods but a thorough understanding of the nature of the disease whose treatment by injection has been assembled in this group of four monographs.

The first of these, on the injection treatment of hernia by Bratrud, is perhaps the least convincing and encouraging. In spite of his careful selection of cases and surely an excellent technic, he reports recurrences in bilateral, indirect inguinal hernias in 31 per cent, the direct inguinal hernias giving a recurrence rate of 40 per cent. This, in the light of our present surgical methods, using silk and local anesthesia, is far too high. The microscopic sections showing proliferation of fibroblasts and extensive fibrosis occluding the hernial openings reveal nothing of the tensile strength of such tissue. Unless such studies become known, one will have to suspect that this fibrous tissue gives way and splits up easily, especially when more five year cures are known. The chapter on trusses is valuable and instructive. That old, handicapped patients who have trouble retaining their hernias with a well fitting truss may do so after a series of injections is a point well taken. While the author has taken a conservative attitude in his indications, further restrictions are bound to come when the limitations of this method are more clearly recognized. Obviously, the general practitioner will be tempted to try such a method instead of a surgical dissection, but this is justified only if his results are not inferior. This has not been shown by the data presented.

The discussion of the injection treatment of hydrocele by Dr. George J. Hoch is short, concise and entirely adequate. He advocates the use of quinine and urea hydrochloride and carefully lists the contraindications to its use.

The monograph on the injection treatment of varicose veins has been written by Harold J. Shelley and is undoubtedly the best monograph on this subject. He has not only completely covered the important literature but shows a complete familiarity with all the aspects of treatment, which permits him to choose or combine surgical methods with treatments by injection.

The fourth treatise on the injection treatment of hemorrhoids is written by Dr. Frank C. Yeomans, one of the most experienced proctologists of the country. He makes it clear that only uncomplicated, internal hemorrhoids should be injected, which comprise about 50 per cent of all cases. The solution preferred is phenol. He stresses the fact that the injections are made in the submucous or interstitial tissues and not into

blood vessels and thus the requirements for a successful solution differ from those used in the treatment of varicose veins.

The printing and illustrations are excellent; the language of the monograph on hernia is careless and contains a few errors in printing. The book is strongly recommended for the general practitioner as a preliminary study followed by guided clinical experience.

Les embolies cérébrales: Études de pathologie expérimentale sur les embolies solide et gazeuse du cerveau. Par Maurice Villaret, professeur à la Faculté de médecine de Paris, et René Cachera, médecin des hôpitaux de Paris. Paper. Price, 32 francs. Pp. 134, with 89 illustrations. Paris: Masson & Cie, 1939.

With the help of a window in the skull of dogs, the authors observed and photographed the pial vessels with a magnification which enabled them to study the arteriolar system and its reaction to cerebral emboli. Solid emboli were produced by the introduction of finely pulverized marble or glass with particles from 80 to 150 microns in diameter into the carotid artery. The immediate reaction to such emboli was a widespread arteriolar spasm, which was present even at a distance from the plugs. These observations were made from the time of embolization up to three hours. In another group of experiments the late vasomotor disturbances from one to 123 days after the embolism were studied. Again there were marked vasospastic phenomena alternating with areas of vasodilatation; the current in the veins was retarded and sometimes reversed. The authors also studied the development of collateral circulation and the "in vivo" appearance of cerebral infarcts. In the second series air was introduced either in the pulmonary vein or in a systemic vein; the vascular system of the pia mater, however, did not react with any vasomotor disturbances to the plugs of air; it simply caused a mechanical obstruction with its natural consequences. In one instance a simple puncture of a pulmonary vein resulted in a demonstrable air-bubble in one of the pial vessels. The authors also presented evidence that air introduced through the saphenous vein may pass through the pulmonary bed and produce cerebral air embolism. Eighty photomicrographs of the pial vessels illustrate the monograph. They convincingly demonstrate the disturbed vasomotricity of the cerebral vessels. The original method of Forbes has been employed here to add to the understanding of cerebral vascular accidents. While the authors do not attempt any clinical deductions, the application of this knowledge to clinical cases of cerebral embolism and possibly other vascular accidents is stimulated. For the physiologist, neurologist and men engaged in research on the vascular system the book is strongly recommended.

John Howard (1726-1790) Hospital and Prison Reformer: A Bibliography. By Leona Baumgartner, M.D., Ph.D. With introduction by Arnold M. Muirhead, M.A. Reprinted from *Bulletin of the History of Medicine*, Vol. VII, No. 5 and No. 6, 1939. Boards, Price, \$1. Pp. 79, with 9 illustrations. Baltimore: Johns Hopkins Press, 1939.

John Howard became interested in conditions in prisons when, shortly before the age of 50, he was appointed high sheriff of Bedfordshire. On attempting to correct prison abuses, he was told that there was no precedent for the expense to be incurred. "I therefore rode into several neighboring counties in search of one; but I soon learnt that the same injustice was practiced in them; and, looking into the prisons I beheld scenes of calamity which I grew daily more and more anxious to alleviate. In order therefore to gain a more perfect knowledge of the particulars and extent of it by various and accurate observations I visited most of the county gaols in England." Howard extended his observations to the prisons and hospitals on the continent and published his reports under the general title of "The State of Prisons in England and Wales . . . and an account of some Foreign Prisons," which passed through a number of editions. The present volume is the bibliographic record of these editions and appended reports, reprinted from the *Bulletin of the History of Medicine* VII, Nos. 5 and 6, 1939, together with a biographic note on Howard by Arnold M. Muirhead, whose collection of *Howardiana* contributed to the completeness of the bibliographic material. There are added sections on biography and criticism, and on contemporary biographic notes and reviews. Howard's method of bringing about reform was to ascertain and publish the facts. The

justice of his cause and the value of his efforts were recognized by his contemporaries, but little headway toward improvement was made against precedent and custom during his lifetime. A contemporary reviewer (1789), commenting on Howard's lazzarettos, reflects the current opinion of his time, somewhat pessimistic but perhaps more prophetic than he knew. "His idea of a perfect hospital contains much (we suspect, very useless) refinement but as it is the refinement of Mr. Howard we shall subscribe to it. . . . On the whole the volume contains many facts of importance and many observations of real utility . . . and we leave it with the best founded expectations that our author's past and future labors will not be wholly in vain." This book is an excellent piece of bibliography.

Étude toxicologique, physiologique et histophysiologique de l'hémoglobine en solution administrée à dose thérapeutique par voie veineuse à des chiens en état d'anémie aiguë par saignée. Par le Docteur Raymond Castagnou, docteur en pharmacie. Paper. Pp. 403, with 58 illustrations. Bordeaux: Imprimerie E. Drouillard, 1939.

This book, in organization and content, resembles a doctor's thesis as the term is understood in the United States. It consists almost entirely of experimental data obtained from a series of fifty-three dogs which were first exsanguinated and then given transfusions with solutions of canine or equine hemoglobin. The object of the study was to ascertain whether solutions of either homologous or heterologous hemoglobin could be used in the treatment of anemia from acute hemorrhage. Extensive data on the freezing-point depression, surface tension, specific gravity, viscosity, osmotic pressure, hydrogen ion concentration and electrolyte content of hemoglobin solutions are given. It was found that such solutions were toxic to many animals, producing mild azotemia with recovery or oliguria and uremia with fatal outcome. An acute syndrome sometimes occurred characterized by collapse, vomiting, diarrhea, hemorrhages from the entire gastrointestinal tract, and death within a few hours. In his toxicologic studies the author, curiously enough, ignored the experimental work of Yorke and Nauss, Baker and Dodds, and DeGowin, Osterhagen and Andersch, which demonstrated a relationship between the reaction of the urine and the occurrence of renal insufficiency from hemoglobinuria. He studied the disappearance of hemoglobin from the blood stream by quantitative estimations of the hemoglobin in the urine and analysis of iron in the various organs. From 2 to 54 per cent of the pigment was excreted in the urine, while the organs most concerned in retaining the iron were the spleen, lungs, liver and kidneys in order of activity. By means of blood gas analysis the author demonstrated that the transfusion of hemoglobin solutions could replace blood as a vehicle for gaseous exchange for from eight to twenty-four hours but that the time was limited by the excretion or immobilization of the hemoglobin. It is also admitted that the toxicity of the hemoglobin solutions is a further disadvantage in applying such a procedure clinically. The illustrations are all photomicrographs of kidneys, lungs and livers showing reactions from hemoglobin. The extreme length of the publication is partly due to the fact that the detailed protocols of individual animals sometimes occupy three or four pages. The book should be of interest to workers in the field but contains little that can be applied clinically.

Elements of Statistical Reasoning. By Alan E. Treloar, Ph.D., Associate Professor of Biostatistics, University of Minnesota, Minneapolis. Cloth. Price, \$3.25. Pp. 261, with illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1939.

"Every set of factual data in science that may be assembled for statistical analysis presents questions which are intimately concerned with the validity of the data themselves. Misinterpretation all too readily flows from routine application of statistical procedures. . . . That which comprises good health at one age may quite properly be regarded as poor health at another age. It is virtually impossible to reach general concordance of judgment in subdividing variation in the state of health into even very few subgroups. . . . The accuracy of mathematical deductions from data must inevitably be limited in some way by the precision and adequacy of the observations themselves. Emphasis must always be laid, therefore, on the necessity for the exercise of critical judgment in the collection

and recording of data. Precision in measurement and care in classification materially enhance the value of observations."

In statements such as these does the author of this addition to discussions of the statistical method in science emphasize the importance of the fundamental data on which the statistical reasoning is based. The present frequency of biologic and medical papers with a statistical bias indicates the need for constant review of the fundamental facts which serve as their basis. In other respects also the author has satisfactorily considered the methodology of statistics as applied to most of the problems faced by the biologist. The mere publication of books on this subject is in itself evidence of at least potential demand; indeed, courses in this field might well be required in the preclinical years, supplemented by practical application during later phases of the medical curriculum.

Varicose Veins. By Alton Ochsner, B.A., M.D., D.Sc., William Henderson Professor of Surgery and Director of the Department of Surgery, School of Medicine, Tulane University of Louisiana, New Orleans, La., and Howard Mahorner, B.A., M.D., M.S., Assistant Professor of Surgery, School of Medicine, Tulane University of Louisiana. Cloth. Price, \$3. Pp. 147, with 52 illustrations. St. Louis: C. V. Mosby Company, 1939.

The subject of varicose veins is admirably covered in this authoritative, concise monograph. With the help of excellent diagrams and photographs, the authors have not only given a complete history of the treatment of varicose veins but have reviewed the anatomy, pathology, physiology, etiology, clinical aspects, examination and treatment of the patient suffering from varicose veins and ulcers. The book is dedicated to Rudolph Matas, "universally acclaimed father of vascular surgery," who wrote an interesting foreword. It is gratifying to see that from the hands of itinerant quacks and a few zealous pioneers this subject is now taken over by surgical teachers of international reputation, whose didactic skill and original research have been so well incorporated to produce the first real textbook in this field. One point should be emphasized in recommending this book to the general practitioner: The injection treatment of varicosities is technically so easy that it has become widely popular with the medical profession. This monograph dwells at length on appropriate diagnostic tests which permit the formulation of a rational therapy. This almost invariably includes a combination of ambulatory ligations at the proper levels with the injections. The wholesale and uncritical injections into dilated veins have often discredited the treatment and incurred unnecessary loss of time and expense for the patient.

The Anatomy of the Nervous System from the Standpoint of Development and Function. By Stephen Walter Ranson, M.D., Ph.D., Professor of Neurology and Director of Neurological Institute, Northwestern University Medical School, Chicago. Sixth edition. Cloth. Price, \$6.50. Pp. 507, with 382 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

In this edition of Ranson's well known and excellent textbook on neuro-anatomy there has been extensive revision in various chapters without material enlargement. The connections of the thalamus with the cortex, brachium conjunctivum, medial lemniscus, spinothalamic tract and secondary trigeminal tracts are discussed in detail. As in the past, emphasis has been on the developmental and functional significance of structure. There are twenty-one chapters. There is a laboratory outline of neuro-anatomy with clinical illustrations. There is an excellent bibliography. The illustrations are beautiful and excellently labeled. Every student as well as every neuropsychiatrist, neurophysiologist and neuro-anatomist should have this book.

Rural Medicine. Proceedings of the Conference Held at Cooperstown, New York, October 7 and 8, 1938. Cloth. Price, \$3.50. Pp. 268. Springfield, Illinois & Baltimore: Charles C. Thomas, 1939.

Although this was primarily a local conference centering about the activities of the Mary Imogene Bassett Hospital at Cooperstown, N. Y., the speakers were drawn from a wide circle. There were four subjects under discussion: rural morbidity, health department programs and school health programs in rural areas, postgraduate medical education in rural areas, and economics of rural medicine. In spite of a well organized program with a wide variety of speakers, the proceedings of the conference are not simply a presentation of divergent views, lacking in continuity and comprehensiveness. The material assembled under these various heads constitutes valuable material for the

study of the problems of rural medicine. It may be significant of an advance in the discussion of medical problems that no speaker attempted to present a panacea. The rather extensive bibliography on rural medicine that is included can hardly be considered either adequate or impartial, but it is at least a beginning which should form a basis for a more complete bibliography.

Die Diät- und Insulinbehandlung der Zuckerkrankheit für Studierende und Ärzte. Von Dr. Franz Depisch. Mit einem Vorwort von Prof. Dr. N. v. Jaglé. Second edition. Paper. Price, 4.80 marks. Pp. 155, with 10 illustrations. Vienna: Julius Springer, 1939.

The author stresses the importance of proper diet in treatment of diabetes, emphasizing the fact that the use of insulin without regard to diet is sometimes harmful. That the cost of insulin to the individual and to institutions is often prohibitive is alone a reason for greater importance being attached to diet, plus the fact that diet is at times even more vital than insulin, are everywhere stressed by the author. It is felt, of course, that the economic side must be considered, but one cannot go as far as the author when he insists that doctors should use insulin sparingly. Certainly the good of the patient and not the cost of the treatment is the first consideration. The author stresses the importance of insulin and protamine zinc insulin being used only by doctors with a thorough knowledge of their therapy. He makes special mention of surfen, a new slow-acting insulin of which we know little in this country because of its failure yet to be introduced into our clinics. Dr. Depisch discusses thoroughly what most of us already know—the preventive side of diabetes by treatment for obesity. At the end of each chapter is a summary pointing out the high lights and making the book simpler to read and to understand. At the end of the book is an excellent summary. A careful reading of this book is a requisite to doctors and medical students.

Gregg Medical Dictation Series: A Course for the Student Who Desires to Become Proficient in Taking Medical Dictation. Volume I: General Medicine. Volume II: Surgery. Volume III: Pediatrics. By Marie Zweegman Yates, Director, Zweegman School for Medical Secretaries, San Francisco, California. Experimental edition. Paper. Price, \$1 per volume. Pp. 90; 88; 89. New York: Gregg Publishing Company, 1939.

When completed, this series will comprise sixteen volumes. Three volumes have now been issued, each a complete unit devoted to a single phase of the subject, such as general medicine, surgery and pediatrics. The object is to acquaint the student with the vocabulary of the subject treated and to present the easiest means of transposition into shorthand symbols. For this purpose, case histories are given in each volume, as well as a glossary containing pronunciations and definitions of words appearing in the Eighteenth Edition of the American Illustrated Dictionary by Dorland, and the Gregg shorthand outlines for them. The series should be most helpful to those for whom it is being prepared.

Elementary Anatomy and Physiology. By James Whillis, M.D., M.S., F.R.C.S., University Reader in Anatomy, Guy's Hospital Medical School, London. Foreword by T. B. Johnston, M.D., Ch.B., Professor of Anatomy, University of London. Cloth. Price, \$3.50. Pp. 342, with 87 illustrations. Philadelphia: Lea & Febiger, 1939.

This is a well balanced elementary treatment of the anatomy and physiology of the body. The text is clearly written and the diagrams and drawings are well designed to make clear to the beginner the main facts of structure of the human body. The physiologic facts presented should enable the student to begin to think of organs to some extent in terms of their functions. Both anatomy and physiology are presented in too elementary a fashion to make the book of much value to American medical students, in view of the organization of courses in these subjects in the United States. It should, however, meet a real need in premedical courses and especially in courses in nursing education. If medical students could enter the first year of the medical course with the knowledge of anatomy and physiology which this book would give them, they could go on to gain a detailed knowledge of the body much more easily than is now true for the majority. Numerous books have appeared in recent years with the avowed purpose of simplifying or abbreviating anatomy. The present volume seems to have accomplished these purposes well for the beginner, while making it obviously necessary for the more advanced student to seek more complete textbooks.

Die Behandlung von Hauttuberkulösen an der Giessener Lupushellstätte 1937/38. Von Dr. Adolf Kreiner. Mit einem Geleitwort von Prof. Dr. W. Schultze, Leiter der Lupushellstätte Giessen. Nr. 73, Tuberkulose-Bibliothek, Beihefte zur Zeitschrift für Tuberkulose. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price, 6 marks. Pp. 61. Leipzig: Johann Ambrosius Barth, 1939.

In this monograph the author reports his experiences in the treatment of 536 cases of cutaneous tuberculosis, chiefly lupus. The advantages of Grenz ray therapy over x-rays are stressed even though the cosmetic results were not always satisfactory. From three to five doses of 4,000 roentgens per field with 9 kilovolts, 20 milliamperes, were found to give the best results. In most cases this treatment was preceded by operative removal of the lupus foci with the electric cutting current, a wire loop being used to remove the entire area with a margin of healthy skin. The treatment is painful and requires local anesthesia and careful after-treatment. Contact therapy with ultraviolet radiation from a water-cooled quartz mercury vapor arc lamp either alone or preceded by electrical ablation is used in lupus in children and in cases that had been previously treated with roentgen rays or radium. Old tuberculin (Koch) is used as an adjunct beginning with minute doses (0.1 cc. of 1:1,000,000 dilution) and is especially effective in papulonecrotic tuberculids. Dietetic treatment with a salt poor, high vitamin diet is not recommended on account of the long duration of the treatment and the expense. Photographs of patients have unfortunately been omitted so that it is difficult for the reviewer to appraise the cosmetic results.

Studies From the Center for Research in Child Health and Development, School of Public Health, Harvard University. I: The Center, the Group under Observation, Sources of Information, and Studies in Progress. By Harold C. Stuart, M.D., and Staff. Monographs of the Society for Research in Child Development, Volume IV: No. 1 (Serial No. 20). Paper. Price, \$1.75. Pp. 261, with illustrations. Washington, D. C.: Society for Research in Child Development, National Research Council, 1939.

This small monograph contains a description of the research and progress at the Center for Research in Child Health and Development at the Harvard School of Public Health. The organization of the center is given in detail, both the physical facilities and the composition of the staff being enumerated. Types and methods of examination are fully outlined and charts are included to indicate the types of dietary information obtained as well as physical data derived from the subjects under study. This monograph is well illustrated, showing the various instruments used for taking the physical measurements. Several family studies are given in detail and are illustrated with photographs and charts. This monograph should be of great interest to those engaged in similar studies.

Histopathology of the Teeth and Their Surrounding Structures. By Rudolf Kronfeld, B.S., M.D., D.D.S., Professor of Dental Histology and Pathology in the Chicago College of Dental Surgery, School of Dentistry, Loyola University, Chicago, Illinois. Second edition. Cloth. Price, \$7. Pp. 504, with 438 illustrations. Philadelphia: Lea & Febiger, 1939.

This is a thorough revision of the first edition, which has been completely rewritten with the inclusion of much new material. Many of the changes in arrangement and content are such as to conform with the recommendations of the Report of the Curriculum Survey Committee of the American Association of Dental Schools. Some of the material included is not strictly histologic in character, as, for example, the first two chapters, on anomalies in the shape and size of the teeth and the physiology and pathology of tooth calcification. This departure is highly commended; indeed, the second chapter should be read carefully by all scientists and practitioners of both medicine and dentistry interested in tooth calcification. The content is liberally inclusive and is a thoroughly adequate presentation of the subject as indicated by the title. The descriptive material is liberally supplemented by well chosen illustrations which are also almost technically perfect. At the close of each chapter is a carefully selected bibliography of the more pertinent articles bearing on that part of the subject. The nomenclature and classification of gingivitis and pyorrhea used by the author are those of Gottlieb; from the point of view of the clinician this is both confusing and unsatisfactory, in spite of the table on pages 316 and 317 differentiating the various forms. However, simplification and clarification

of this situation continues to be a problem awaiting solution. The influence of the enamel cuticle in protecting the tooth from the onset of dental caries (page 106) would seem to be overemphasized. The implied acceptance of Bunting's opinion that the only significant difference thus far known between caries-free and caries-susceptible persons is in the number of *Bacillus acidophilus* organisms in the mouth is hardly justified in the light of current chemical research. In spite of these and possibly other minor criticisms, this is without doubt the leading textbook in this field in the English language.

German-English Science Dictionary for Students in the Agricultural, Biological and Physical Sciences. By Louis De Vries, Professor of Modern Languages, Iowa State College, Ames. With the collaboration of Members of the Graduate Faculty. Fabrikoid. Price, \$3. Pp. 473. New York & London: McGraw-Hill Book Company, Inc., 1939.

The author of this German-English science dictionary received the cooperation of many of his colleagues in its compilation. The number of sciences that had to be studied necessitated a rigid selection of words. Not all the names of animals, plants, insects or chemical compounds have been included. These omissions will of necessity impair somewhat its usefulness but no doubt some of them will be corrected in future editions.

An Introduction to Modern Genetics. By C. H. Waddington, Sc.D., Fellow of Christ's College, Cambridge. Cloth. Price, \$4. Pp. 441, with 160 illustrations. New York: Macmillan Company, 1939.

The aim of this book is to give an account of the more important recent developments in the field of genetics. Although the literature on the subject is most extensive, the author has succeeded in presenting a relatively brief account. On the whole, however, the book seems more suitable for collateral reading in connection with a college or university course in genetics than for the general perusal of the casual reader even when possessed of considerable biologic background. To the physician the brief chapter on human genetics is naturally the most interesting.

Peripheral Vascular Diseases: Diagnosis and Treatment. By William S. Collins, B.S., M.D., Chief of the Clinic for Peripheral Vascular Disease, Israel Zion Hospital, Brooklyn, and Nathan D. Wilensky, M.D., Assistant in Clinic for Peripheral Vascular Disease, Israel Zion Hospital. Cloth. Price, \$4.50. Pp. 243, with 77 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1939.

This monograph has been written to offer the physician a reference work which may aid him in the management of peripheral vascular disease. For the most part this task has been accomplished. Some of the chapters, such as the one on peripheral vascular sclerosis, follow closely the teachings of Winternitz, are beautifully presented and are profusely illustrated. Other subjects, such as congenital vascular anomalies, aneurysms and varicose veins, are hardly mentioned. The surgical treatment of acute arterial embolism is not encouraged. The classification of peripheral vascular disorders is somewhat cumbersome and overlapping. While certain tests and apparatus which the authors have devised are treated in great detail, others are less favorably treated, which gives the unbiased reader a feeling of false proportions. The design and printing of the book and the colored plates satisfy the highest standards of medical publications.

Dentistry for Children. By John Charles Brauer, D.D.S., A.B., M.Sc., Head of Department of Preventive Dentistry, University of Iowa School of Dentistry, Iowa City. With Special Chapters by L. B. Hiley, B.A., D.D.S., M.S., Professor, and Head of Department of Orthodontics, School of Dentistry, University of Iowa, and Julian D. Boyd, M.S., M.D., Associate Professor of Pediatrics, College of Medicine, University of Iowa. Cloth. Price, \$6.50. Pp. 373, with 335 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

This book considers the many problems found in the modern dental office. The subjects are presented in a concise manner, and special mention is due the illustrations, which are so carefully presented as to make many pages of interesting study. There is sufficient review of the basic anatomy and structural parts to be interesting, but the author does not "fill in" with lengthy reviews. Instead, the newer more vital subjects in connection with preventive dentistry together with chapters devoted to instructive suggestions in managing the child patient are thoroughly treated. Also the correlation of the author's writings with those of the orthodontist and the pediat-

trician insures thorough coverage of the subject from every available angle. Chapter 9, devoted to preventive orthodontics, is actually saturated with helpful suggestions for the solution of the problems of the general practitioner. The illustrations and explanations offered in this chapter would be exceedingly fine for the practicing dentist to have available in his office for more fully explaining to the public their various problems. The book is highly recommended to the student as a textbook, to the practicing dentist as a reference book, and to both as an indispensable guide for better understanding the unique field of children's dentistry.

Die Zuckerkrankheit. Von Prof. Dr. Wilhelm Falta. Second edition. Paper. Price, 7 marks. Pp. 154. Berlin & Vienna: Urban & Schwarzenberg, 1939.

This little manual on diabetes includes discussions of diagnosis, differential diagnosis, pathogenesis, dietetic management, complications and the use of the old and newer insulins. It reflects largely the views of its author. For American readers the excellent books available in English will probably prove more useful.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alleged Negligence in Treatment of Chest Wound by "Visiting Surgeon" of Hospital.—The plaintiff, by his next friend, sued the defendant physician to recover damages for alleged malpractice. The trial court directed a verdict for the defendant and thereafter reported the case to the Supreme Judicial Court of Massachusetts on a stipulation of the parties.

When about 11 years old the plaintiff, in the early part of January 1935, was injured while coasting. A runner of the sled of another boy struck him, went through his clothing and made a wound in his chest. He was brought to a hospital, where he was examined by the defendant, who was "visiting surgeon," and another physician who was "house officer." The defendant directed the taking of roentgenograms, the results of which were negative. Under his direction, the wound was washed with "green soap" and closed by sutures, and antitoxin was injected in the patient's arm. The patient remained in bed at the hospital for nine days, during which period he was treated daily by the "house officer" and seen by the defendant on his daily rounds of the hospital. After an eleven-day stay he went home on January 14 and thereafter for a period of about two months visited the outpatient department of the hospital weekly and was treated by the "house officer." During this period, pus appeared in the wound and on two occasions the "house officer" picked from it some threads. At the end of three months the wound was only partially healed and the patient was taken to another hospital where an examination disclosed a chronic sinus of the chest wall from which was removed a small piece of wool fabric. Two weeks thereafter the wound had healed.

The defendant's evidence tended to show that on examining the patient at the time he entered the hospital the defendant found a lacerated wound over the left breast. The chest wall was exposed and there was some bleeding. The defendant directed the "house officer" to give the treatment earlier described, admonishing him to be careful in any scraping of the wound because the chest wall was so thin. The purpose of the treatment directed and given was to get out all the foreign material possible, to give anything left in the wound room to get out, and to drain and help evacuate the wound of pus or foreign material. The defendant never saw the patient after he left the hospital. The defendant testified that when the patient left the hospital the wound was discharging serum, not pus, and that such a wound would take three or four months to heal; that the treatment given was good surgical treatment and that no more could have been done at the hospital than was in fact done.

Viewing all the evidence in the case in the light most favorable to the patient, the court said, a basis was not afforded for finding the defendant negligent. The precise relationship between the defendant and the "house officer" was not disclosed by the record but an inference was warranted, in the opinion of the court, that it was the latter's duty to administer to patients such treatment as the defendant directed. There was nothing in the record to indicate that the defendant had anything to do with the outpatient department or had any supervision over treatment there given to patients. The patient contended that the defendant was negligent in not discovering and removing from the wound, at the time of the examination, the bit of wool fabric which was removed several months later. If the testimony of the defendant were accepted, the court said, there was adequate reason for not ascertaining at that time whether any foreign matter was in the wound, and the course followed by the defendant of awaiting the partial healing of the wound and the formation of a sinus was prudent and proper. If his testimony were rejected, there was no expert testimony on which to base a finding that the conduct of the defendant was improper.

The fact that pus appears in a wound which is being treated by a physician does not warrant the finding that he was negligent; infection may arise regardless of the care used by the attending physician. There was here no evidence that the pus was seen before the patient left the hospital on January 14. There was no evidence of any specific act of the defendant or of the "house officer" that introduced any septic matter into the wound. The inference was warranted, the court continued, that foreign matter caused the appearance of pus but not at a time when the defendant was treating the patient or was supervising his treatment. Pus appeared while the patient was being treated in the outpatient department. The defendant had nothing to do with that department.

Since the evidence in the case did not warrant the submission of the case to the jury, judgment was entered for the defendant.—*Tallon v. Spellman (Mass.)*, 19 N. E. (2d) 33.

Accident Insurance: Death from Chloral and Bromide Poisoning as Accidental.—The insurance company promised to pay to the beneficiary certain benefits if the insured died from bodily injuries effected directly and independently of all other causes through external, violent and accidental means which produced a visible contusion or wound on the exterior of the body. The insured died as a result of taking a medicinal compound containing cannabis, chloral hydrate, potassium bromide and extract of hyoscyamus. The company refused to pay the benefits and the beneficiary sued and obtained judgment in the trial court. The company then appealed to the court of appeals of Tennessee, western section.

The insured was so constituted physically that a comparatively small quantity of intoxicating liquor, while not making him drunk, would result in his being rendered highly nervous after the effect had worn off. To relieve this condition, which occurred at irregular periods only, he was accustomed to taking the medicine described, which he procured at a drug store without a physician's prescription. On the evening of Nov. 27, 1936, the insured had several drinks of gin and beer. He was not rendered noticeably intoxicated but nevertheless was so nervous the following day that he remained in bed. That night his wife telephoned to a neighborhood drug store and ordered some of the medicine. A 2 ounce (60 cc.) bottle of it was sent, with directions written on it to take "two teaspoonsful as needed." The insured was given a dose at 7:30 p. m. and another dose of 2 teaspoonfuls about midnight. He apparently took some more of the medicine about 12 noon of the following day and another dose of 2 teaspoonfuls about 3 o'clock. About 6:30 p. m. his wife noticed that he had a peculiar look about his eyes—that his eyes "looked kind of glassy"—and called in a friend of the family. Shortly after the arrival of this friend, the insured took another dose of the medicine (just how much does not appear in the record), staggered back to his bed, lay down on it and went into a deep sleep. A physician was immediately summoned and found the insured in a serious condition. "He had a pallor and his pulse was thready and weak, respiration shallow." The insured was immediately taken in an ambulance to a hospital where his

stomach was washed out and he was given cathartics and epinephrine. He died while on the emergency table, death being attributed to chloral and bromide poisoning resulting from the cumulative effect of the medicine.

The insurance company, in refusing to pay the benefits, insisted that the death was the natural result of an act in which the insured intentionally engaged and that therefore it was not accidental. The appellate court, however, was unable to agree to the contention that the insured actually took what he intended to take. True, the court said, he intended to take the identical liquid which he took, and it may be in precisely the quantity intended. It was clear to the court, however, that in so doing he meant to take a harmless "nerve remedy" and, based on his previous experience, thought that was what he was doing, whereas what he in fact took, instead of being harmless, was poisonous in the quantities taken. His ignorance of this fact introduced an entirely unforeseen and unexpected element into an act which was in other respects intentional, and hence rendered it "accidental."

The insurance company further contended that there was no proof of a visible contusion or wound on the exterior of the insured's body evidencing the injury that caused his death and hence recovery was not warranted even though the injury was effected by accidental means. The beneficiary insisted that the evidence was sufficient to meet the requirements of the policy, stressing the facts that when the insured staggered to the bed after taking the last dose of the medicine he lay down "and went into a deep sleep and his mouth flew open and he snored," that his features were "very white" and that "his head was drawn back." The words "contusion" and "wound," said the court, are of well known, commonly understood import which must be given effect. To the court there was no reasonable basis for the view that a pallid face and drawn head are within that meaning.

The judgment of the trial court for the plaintiff was therefore reversed and the case remanded for a new trial.—*Travelers Ins. Co. v. Ansley (Tenn.)*, 124 S. W. (2d) 37.

Optometry: Duty of Optometrist to Detect Disease of Eye; Liability of Corporate Employer of Optometrist.

—The defendant jewelry and optical corporation operated a department, in charge of a licensed optometrist, wherein the eyes of customers could be examined and glasses prescribed. The plaintiff's eyes had been hurting her for some time and on seeing the defendant's advertisement in a newspaper, she visited the optometrist in charge of the department, May 17, 1935. The optometrist examined her eyes and prescribed lenses which, however, failed to relieve the condition. On several occasions, according to the testimony introduced on her behalf, she returned to the optometrist and complained that the glasses caused her eyes to hurt and each time she was assured that the glasses would remedy her ailment when she became used to wearing them. On November 2 the plaintiff returned again to the optometrist and complained that she could not see out of one of her eyes. An examination by the optometrist disclosed that the sight of her right eye was completely gone and he then advised her to see a physician. The physician whom she consulted discovered that she was suffering from glaucoma, which had caused a detached retina of her right eye and which was at that time affecting her left eye. Subsequently her right eye was removed and her left eye treated in order to save it. She then brought suit against the corporation and the optometrist. Before the case was given to the jury, however, the case against the optometrist was dismissed and thereafter the trial court gave judgment for the defendant corporation. The plaintiff appealed to the Supreme Court of Alabama.

The first question discussed by the court was whether the relationship of master and servant existed between the corporation and the optometrist. When an optometrist undertakes to make an examination of the eyes, the court said, with a view of determining whether glasses will be of aid to his patient, he must exercise his professional or scientific skill, knowledge and judgment and he cannot be directed by an employer who has no such knowledge. But this does not mean that the employer, whose business the optometrist is conducting, is not answerable for the negligence of the optometrist

resulting in injury to a third person, who has gone to the employer's place of business for an examination of her eyes and to be fitted with glasses. It was the defendant's business, under the control of its optometrist, it is true, but the defendant undertook for a pecuniary reward to render competent and proper optometric services. For all practical purposes, the defendant was engaged in rendering optometric service to the public. The defendant cannot, therefore, escape liability because of the independent character of the agent's or servant's business. The defendant was bound to see that those who sought examination of their eyes and the fitting of glasses received proper attention and service, and for any injury or damage to the defendant's customers, proximately caused by the want of skill or negligence of the optometrist, it, the defendant, is liable.

After reviewing several definitions of optometry, the court concluded that the optometrist in this case was not required, or even authorized, to diagnose and treat diseases of the eye. The optometry act of Alabama prohibits any optometrist from administering drugs in any form, from practicing, or claiming to practice, medicine or surgery in any sense, or from using any title or appellation intended or calculated to indicate the practice of medicine or surgery. Clearly, the court said, the duty resting on the optometrist was to examine the plaintiff's eyes for the "purpose of ascertaining any departure from normal (having reference to vision), measuring its functional powers, and adapting mechanical means for the aid thereof." If, however, in the performance of those duties, it would be apparent to a skilful optometrist that there existed in the eye a disease or malformation, the court inferred that it would be the optometrist's duty so to advise his patient in order that the proper medical or surgical treatment might be had. The evidence in this case, however, convinced the court that the disease of the plaintiff's eyes was not such a disease as should have been detected by a skilful optometrist. The corporation's optometrist, therefore, was not negligent in failing to detect it.

Since there was no breach of duty owed by the corporation to the plaintiff, the judgment for the defendant corporation was affirmed.—*Hampton v. Brackin's Jewelry & Optical Co., Inc. (Ala.)*, 186 So. 173.

Privileged Communications: Wife of Physician Who Acts as Assistant Within Rule.—Where a statute, said the criminal court of appeals of Oklahoma, provides that a physician or surgeon shall be incompetent to testify as to any communication made to him by his patients with reference to any physical or supposed physical disease, or any knowledge obtained by a personal examination of any such patient, the same rule applies to the wife of the physician or surgeon who is his assistant in his office and by reason thereof hears the communication or sees the examination.—*Williams v. State (Okla.)*, 86 P. (2d) 1015.

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Activities Associated with Onset of Coronary Occlusion.—In this paper Master and his associates offer evidence at occlusion of the coronary artery occurs irrespective of physical activity. They analyzed 1,440 attacks of coronary preceding the attacks, the time of day when the attacks occurred, the patients' occupations and other associated factors. The distribution of occupations was approximately the same as that in the general population; therefore occupation and social status did not predispose to coronary occlusion. The circumstances preceding the onset of symptoms in 890 cases were sleep 22.3 per cent, rest 31.1 per cent, mild activity 20.2 per cent, moderate activity 8.5 per cent, walking 15.8 per cent and unusual exertion 2 per cent. Correlation of these percentages with the number of hours spent daily by the ordinary person in the same occupations indicated that the circumstances were coincidental and that none of them was causally related to the coronary occlusion. Thus coronary occlusion occurs irrespective of the state of physical activity of the body. Associated factors in 930 cases were meals 9.9 per cent, emotional excitement 5.6 per cent, surgical operation 6.6 per cent, infection 4.3 per cent and miscellaneous factors 1 per cent. It was concluded that, with the possible exception of surgical procedures, these factors did not play a role in the pathogenesis of coronary occlusion. Only two attacks of coronary occlusion were associated with trauma. Detailed histories of the activities and emotional state of patients for hours, days and weeks preceding attacks confirm the belief that physical activity and excitement are not factors in the onset of coronary occlusion. Sixty patients sustained an attack of coronary occlusion after having been bedridden for weeks or months. The time of onset was ascertained in 722 cases. Equal numbers occurred during the afternoon, evening and night and were distributed throughout all the hours of the day, with attacks at 2 a. m. and 10 p. m. This also indicates that activity is not a factor in the precipitation of coronary occlusion. Premonitory symptoms of the attack, such as pain in the chest, dyspnea or weakness were present in eighty of 170 cases. There is no evidence that physical effort or excitement produces intimal hemorrhage in the coronary arteries, which is the usual forerunner of thrombosis and occlusion. Intimal hemorrhage is the end result of the progressive, degenerative arteriosclerotic process and is probably a fortuitous event. It was found at necropsy as frequently in patients who had been bedridden prior to the occlusion as in those who were physically active.

*Carcinoma of Lung: Analysis of Seventy-Four Autopsies. R. D'Aunoy, B. Pearson and B. Halpert, New Orleans.—p. 567.

Carcinoma of Lung.—D'Aunoy and his associates state that seventy-four cases of primary carcinoma of the lung were encountered in 6,623 necropsies on persons more than 1 year of age. Sixty-eight of the growths occurred in men and six in women. The age range was from 21 to 75 years. The average duration of illness was five months. One patient died in the third, four in the fourth, thirteen in the fifth, thirty-three in the sixth, nineteen in the seventh and four in the eighth decade of life. In almost half of the cases the primary growth was located in one or the other bronchus. Thirty-seven of the seventy-four carcinomas were composed of squamous cells, twenty-one of reserve cells and sixteen of columnar cells. The problem is emphasized by many recent publications. There is an apparently wide variance in the conceptions of individual authors as to the histogenesis and structure of carcinoma of the lung as no uniformity has yet been attained in classifying these growths. The difficulty may be superficial rather than essential. In the authors' opinion a classification on a histogenetic basis, combined with a nomenclature derived from the cell making up the growth, rather than from the structure which the cell forms, will go far toward simplifying the problem. The occasional overlapping of groups is not unexpected, since all carcinomas of the lung, they believe, are derived from a common ancestor cell, the reserve cell.

Effect of Posture on Peripheral Circulation.—Nielsen and his co-workers report that a passive change of body posture by a tilting from the horizontal to a feet down position (45 degrees from the horizontal) produces a peripheral vasoconstriction in subjects not adapted to warm environments. The degree of vasoconstriction increases with progressively warmer environments and higher angles of tilting. Higher angles of tilting or extremely hot environments are associated with a tendency to collapse. A rise of internal body temperature, roughly proportional to the degree of vasoconstriction, occurs in the vertical position and may be functionally associated with the stimulus to increased evaporation. The disturbance of the heat-regulatory function due to vasoconstriction in the tilted position is, to a certain degree, compensated by an increase in evaporation. Except under severe conditions, toe temperatures change in an opposite direction to general cutaneous temperatures, possibly involving a protective mechanism against local chilling.

Immunization of Peritoneum.—Collier and Rife point out that during the last ten years three immunizing agents have been employed extensively for immunization of the peritoneum. These are (1) the vaccine developed by Steinberg and Goldblatt, (2) the vaccine prepared by Bargen and (3) the amniotic fluid preparations originally suggested by Johnson. Such factors as the species of laboratory animal used, the type and dose of immunizing substance employed and the time and mode of its administration make it difficult to compare the observations of one investigator with those of another. It is logical to assume that the peritoneum of one animal will not react in the same manner as that of another, and the peritoneums of animals will all differ in some respects from that of man. As yet no adequate control series has been reported. From a clinical point of view, the newer concept of the protective value of the exudate in peritonitis has a practical value. In operations done on patients with peritonitis it would seem harmful to carry out manipulations designed to wipe or wash away exudate that is part of a protective mechanism against the infection. If free exudate is removed it must be done in the gentlest fashion, by careful aspiration. The authors can see no reason for the routine use of any of the substances suggested to increase the immunity of the peritoneum. If patients are properly prepared for operation and if the operation is carried out with careful meticulous technic, peritonitis rarely supervenes. Some substance that will produce rapid local leukocytosis is of value in those instances in which, because of accident of operation or disease, the large intestine is opened. The authors' experience in these circumstances has been most satisfactory with colibactragen (Steinberg). They feel that it has a distinct value when used in the stage of contamination and that it has little or no value once the infection is established. Postoperative peritonitis in cases previously without infection is usually due to errors of operative technic that cannot be corrected by the introduction into the peritoneum of anything except better surgical technic.

Malignant Disease of Colon.—Allen and Welch reviewed 634 patients with cancer of the colon admitted to the Massachusetts General Hospital from 1925 to 1938 inclusive. Of these, in 365 the colon was resectable. This operability can be increased only by earlier diagnosis and by abandonment of the idea that the disease is incurable or that the patient cannot stand the operation. Many times help is denied until obstruction sets in or the patient becomes moribund from perforation or hopeless extension of the disease. In considering the various locations of cancer of the colon and the operative procedures giving the most satisfactory outcome, the authors state that each surgeon must adopt the method that gives him the best result. Gross contamination of the peritoneal cavity must be avoided. The diseased area must be removed and, in most instances, continuity of the intestine reestablished. The blood supply to the anastomosed ends must be preserved. Sutures must approximate the serous coats of the intestine, and the mucous membrane

must be inverted. There must be no tension on the suture line and no drains resting near it. Traps in the mesentery must be closed and raw surfaces peritonized when possible. Proximal complementary decompression must be established if not provided by a previous procedure. If to these rules good general surgical principles are added the results will be satisfactory. The authors have found that two stage procedures have lowered their mortality. They believe preliminary proximal operations should be done routinely for malignant lesions of the large intestine whether obstruction does or does not exist, and regardless of the age or condition of the patient. Too many "good risk" patients have succumbed to one stage operations on the intestine. The hospital stay of the patient operated on in two stages for cancer of the colon is increased on an average of ten days, but the fatal complications of peritonitis and pneumonia are materially reduced. The mortality from radical operation was approximately 20 per cent in one stage procedures as compared with 13 per cent in the two stage operations.

Allergy in Multiple Sclerosis.—Baer and Sulzberger undertook to study patients with multiple sclerosis in order to determine how many had an atopic hypersensitivity. This type of allergy, which is clinically represented by asthma, hay fever and atopic dermatitis, is characterized chiefly by (1) a high incidence of atopic conditions in the familial as well as in the personal history, (2) wheal responses to scratch and intradermal tests with the protein fractions of foods, inhalants and other materials, (3) eosinophilia in the blood and (4) frequent observation of passive transfer antibodies or reagins (Prausnitz-Küstner reaction). Atopy is only one of many characteristic forms of allergy known to appear in man (others are, for example, contact allergy, tuberculin allergy and various forms of drug allergy). The authors made their studies on forty patients with multiple sclerosis. On all forty patients, scratch tests were made with from sixty-four to seventy common food allergens and with thirty-four common inhalant and other allergens. Histories of thirty of the forty patients were taken with regard to the familial and personal incidence of atopic conditions, the ingestion of drugs and exposure to occupational as well as other environmental substances prior to the onset of the disease. From the remaining ten patients no exact histories could be obtained. Of the thirty patients with multiple sclerosis who were completely studied, ten, or 33 per cent, presented evidence of personal or familial atopic disease or positive wheal reactions to skin tests or both. When these figures are compared with those in the literature relating to the incidence of atopy in an unselected population, it will be seen that these results correspond with the high average values submitted by investigators who have performed similar studies on unselected groups. The authors conclude therefore that, with the criteria and methods described and with allowance for the factor of error present in a series of this small size, their results in the forty cases of multiple sclerosis do not demonstrate a significant increase over the normal incidence of atopy. This statement does not, of course,

elude the possibility that in an occasional instance multiple sclerosis-like symptoms may be caused by an atopic mechanism. Nor do these results in any way preclude the possibility that some nonatopic form of allergy may play a role in multiple sclerosis.

Follow-Up Study of Patients with Schizophrenia.—Rennie studied 500 patients exhibiting a typical picture of parergastic disorder, commonly designated as schizophrenia or dementia praecox. This group is made up of the patients admitted between May 1913 and May 1923. Of the 500 cases selected for the study, the author has been unable to get adequate facts in only forty-four. Concerning 456 patients he has some statement of the course of the disease, ranging from one to twenty-six years after hospitalization. The method of follow-up study employed was to trace the patient's present status by the use of a letter of inquiry to the patient, relatives or family physician; a personal interview by a staff member, or an interview with the patient or family by a social worker employed for this project. A number of patients were followed by all three methods. In discussing the results of this investigation, the author says that at the time of discharge from the clinic 42.7 per cent were well or improved, whereas 57.3 per cent left the hospital unimproved. The course of the illness seems more favorable for women than for men. At the end of twenty years the picture is less favorable than at the end of nine years or at the time of discharge. After twenty years, 27 per cent of the patients show recovery; an additional 13 per cent give evidence of some productivity. There is great variability in the course of the disorder as regards rehospitalization; 33.5 per cent of the total series of patients were never able to leave a hospital; 32.6 per cent were never readmitted to any hospital. While rehospitalization is frequent, this does not necessarily affect the final outcome. For the majority of the patients who recover a single brief period of hospitalization is the rule. There are exceptions to this, in that one fourth of the total number had a period of readmission to a hospital. One patient, after ten years of psychotic behavior in a hospital, appears to have been completely recovered for eight years. Another patient, after eight years of hospitalization, appears to have been completely recovered for fourteen years. In a few other cases there have been as many as five hospitalizations before recovery was effected. Thus, a second or even a third or fourth hospitalization does not necessarily spell poor prognosis. Nonetheless, it is striking that the period of hospitalization for the recovered group is for the most part less than a year. In marked contrast to the relatively brief period of hospitalization and to the single admission of the majority of the recovered patients are the observations on the group of permanently hospitalized patients. For the most part these persons show a protracted and uninterrupted period of hospitalization. However, gaps of time between the first and the permanent hospitalization occur with 35 per cent of the group. Permanent recovery is difficult to predict, even after long years of apparent well-being. These observations tend to reemphasize the fact that extreme caution must be exercised in offering prognosis in cases of schizophrenia.

Ascorbic Acid Deficiency and Intestinal Fusospirochetosis.—According to Woolsey and Black, a microscopic study of sections of intestines obtained at necropsy in twenty-four cases of intestinal disease (including diphtheritic and ulcerative colitis, typhoid, dysentery due to Flexner's bacillus and enteritis due to Giardia and Ascaris) revealed fusiform bacilli in twelve instances. In only two of these were Levaditi stains available, and in these spirochetes were seen. In all but two of the twelve cases in which fusiform bacilli were found there were infections which could have caused a break in the intestinal mucosa. All of these patients had been on a diet deficient in

ascorbic acid. This type of diet lowers the resistance of the intestines to infections. The manner in which this resistance is lowered is probably complex, but the authors' experiments on animals receiving a diet deficient in ascorbic acid showed numerous small hemorrhages in the intestines, indicating that at times these hemorrhages are sufficiently profuse to cause necrosis and thus a break in the mucosa which allows the organisms present to gain a foothold. What part this mechanism plays in clinical cases is difficult to evaluate. The evidence of other causes at necropsy does not preclude the possibility that some agent other than the ascorbic acid deficiency may have been present before the fusospirochetal infection. However, the work of Koch indicates that extreme ascorbic acid deficiency leads to definite intestinal lesions with fusospirochetes present. When a break in the mucosa of the intestines is caused by parasites, bacteria or a deficiency of ascorbic acid fusospirochetal organisms, if present, may cause further damage. However, at present there is no indication that the intestines can be damaged by fusospirochetes without the aid of some other factor.

Metabolism of Androgens in Women.—Hamblen and his colleagues determined the urinary androgens, by a modification of the colorimetric method of Oesting, in a group of twenty-seven women with various levels of ovarian function. In all, 672 twenty-four hour specimens of urine were titrated. Daily titers of the same woman varied markedly. Normal androgenic titers were obtained in five healthy women, aged 21 to 43 years, who experienced cyclic menses; in two women who had had operations involving hysterectomy with ovarian conservation and in five women who had had operations involving hysterectomy and bilateral oophorectomy; in two women, 14½ and 19 years of age, with belated menarches who were staturally and sexually retarded, and in two women, aged 17 and 29 years, who had functional menometrorrhagia associated with various degrees of endometrial proliferation and differentiation. Androgenic titers tended to be high in four women, from 16 to 30 years of age, who had had episodes of amenorrhea, which ranged in duration from four months to five years, and in five women, from 42 to 74 years of age, whose last episodes of uterine bleeding had occurred from nine months to twenty-six years before the

present observation. Injections of testosterone propionate, which varied as to single doses from 10 to 100 mg. and as to number from one to ten, resulted in definite elevations of androgenic titers. The recoveries of the androgen injected ranged from 7.6 to 71 per cent. Intensive estrogenic therapy of two patients caused definite decreases in androgenic titers. From the data reported it is suggested that the chief source of androgens in women is not the ovaries but most likely the adrenals. The complexional coloring and the androgenic titers of women apparently are related. The increased androgenic titers of some women who have periods of amenorrhea may be of diagnostic, prognostic and therapeutic import. An apparently increased production of androgens during the early postmenopausal period may signify the existence of another mechanism for stabilization of pituitary function after ovarian effects have become minimal. The androgens may play an active part in the production of the regressive alterations in the aging sexual system of women.

Effects of Endocrines on Vaginal Smear.—Rothermich endeavored to demonstrate what effect, if any, androgen has on the human vagina as revealed by the vaginal smear. Eleven menopausal women receiving estrogen responded with the typical follicular smear. In eleven similar women treated with testosterone the vaginal smear, if atrophic beforehand, showed no change; if previously follicular in character, the smear regressed to the atrophic type, in which state it persisted. The stimulative effect of estrogen could be entirely nullified by the simultaneous administration of adequate amounts of testosterone. The following conclusions seem indicated: Androgen has no direct stimulating action on the human vagina. Androgen nullifies, counteracts or neutralizes the usual action of estrogen on the human vagina.

Insulin in Treatment of Bone and Joint Tuberculosis.

—Because some children suffering from bone and joint tuberculosis cared for in a convalescent home affiliated with the University of Chicago failed to gain in weight insulin therapy was recommended. Nichols and Compere selected fourteen patients with tuberculosis and one with bilateral Legg-Perthes disease, from 3 to 13 years of age, for this adjunct therapy. To each of these patients from 2 to 5 units of insulin was administered twenty minutes before each meal. In each instance the patient manifested more interest in his food. For the first time, some complained that they were hungry. Twelve of the fifteen patients gained from 1 to 3 pounds (0.45 to 1.36 Kg.) in weight. In three of the twelve cases there was no consistent gain in weight until after the injections had been discontinued. There was a simultaneous improvement in the general appearance and well-being of the patients. The authors are not able to postulate conclusions from so few cases. It seems to them that injection of insulin is not indicated as a routine procedure in the treatment of bone and joint tuberculosis except for patients

who are finicky eaters and who, under the best of environmental conditions, fail to gain or actually lose weight.

Orthopedic Treatment of Strümpell-Marie Arthritis.—Swaim reports his results in 106 cases of Strümpell-Marie arthritis observed over twenty-two years. The sacro-iliac joints were fused early in all of the 106 cases. After fusion was complete, the disease stopped. In some cases the hips became fused also. The author's theory has been that ossification represents the result of nature's method of permanent immobilization of the spine to prevent strain and motion and inflammation in the ligaments. Therefore he believes that orthopedic treatment should begin at least within the first three years, although much can be done within nine years. Prior to 1930, forty-five patients had been treated by orthopedic measures in an attempt to prevent the usual deformity of rounded thoracic spine, flat upper part of the chest and buckled body, with protruding head and sometimes with fused hips. The method of correcting posture was as follows: The patient was kept recumbent, and the spine was gradually hyperextended in bed, first by removing the pillows under his head until he was either flat or as straight as possible; second by using plaster half-shells to support and to stretch the spine. Relaxing hot fomentations were applied to the whole spine twice daily for twenty minutes, and corrective exercises to straighten the body and to expand the chest were taught and supervised morning and evening. When the back was as straight as it seemed possible to make it, steel braces which drew the shoulders back were fitted, or short spring braces with elastic shoulder straps were tried; even corsets were used at times to reinforce the braces. Thirty-five of the forty-five patients had completely fused spines, and thirty-one had poor posture in spite of treatment. The results were so unsatisfactory from a postural standpoint that a better method of preventing deformity had to be devised; plaster jackets were tried. It was found that after the patient was completely immobilized in a jacket for several months, motion in the spine was increased rather than lost by the fixation. With the exception of the use of the jacket, no change was made in the previous treatment. If the spine was not straightened by the end of two weeks a jacket was applied and was renewed at regular intervals. The jacket was kept on uninterruptedly for several weeks, until there was no spasm. Then only were new jackets made. Plaster jackets were renewed until the best possible correction was obtained; then a more permanent leather jacket (stepped in back and laced in front) was made on a plaster model. It was cut high in front and low in back and, being waxed, was designed to last for several years. In most cases it was worn day and night. After each plaster jacket was hard a greater lordosis was attempted. Walking was encouraged as the adductor spasm disappeared. The results were encouraging. The spasm and pain disappeared during the first few days, and the general condition improved with the lessened pain and better nights of rest. From the patients' standpoint, the jackets have given the greatest relief to the hips, ribs and neck. From the orthopedic point of view, postural deformity has not occurred, chest expansion has increased and the general health has been better. Sixty-two patients have worn the leather jackets. All became symptomatically better. They were made more comfortable, except three who were uncooperative. All have preferred to wear their jackets rather than to go without them. Conclusions about the physical effects are drawn from twenty-three patients who have worn jackets for from four to nine years. Good posture was maintained in five, improved in fifteen and lost in three; one of these refused the jacket after two years, one cut his jacket in front so that it no longer gave any support and one was uncooperative. No new hip trouble developed in any of the sixty-two cases. Seven of the eleven patients with hip symptoms who wore their jackets from four to nine years became completely symptomless, three patients with fused hips showed no change and one patient was unaccountably worse. Chest expansion decreased in seven cases, was unchanged in two and increased in fourteen. Weight increased in twenty cases, remained the same in two and decreased in one. Sixteen patients are working, six are at home (unemployed but looking for work), and one died of carcinoma of the breast. The study definitely suggests that ossification is much less rapid in patients treated with jackets. The results for such patients were superior to those for the forty-five previously treated without jackets.

Epiphysitis of Os Calcis.—Simon and Williamson warn that in children, particularly in boys, between 7½ and 17 years of age the occurrence of painful heels should suggest the possibility of epiphysitis of the os calcis. The characteristic x-ray observations are fragmentation, rarefaction, narrowing and irregularity in outline of the epiphysis, with later excessive calcification. The condition is self limiting, and recovery occurs spontaneously when the epiphyses unite at about 17 years of age. The etiology has not been definitely established, but the role of trauma seems to be of some significance. Trauma, infection, nutritional disturbances, developmental abnormalities, dislocation in innervation and endocrine imbalance have all been blamed for the condition. It is possible that a combination of several of these factors is sometimes responsible. It is also logical to assume that the cause is not the same in every case. The wearing of sandals, rubber-soled shoes or no shoes at all has been a rather constant observation.

Bacterium Nephrophorum Agglutinins in Serum of Colitis Patients.—Dack and his co-workers collected seventy-six specimens of serum from thirty-six patients in different stages of chronic ulcerative colitis. There was a definite correlation of the appearance of Bacterium nephrophorum with the agglutinins for this organism and with the severity of the disease. The severer the disease the greater the ease of isolation of the bacterium and demonstration of nephrophorum agglutinins. The inability to find the organism in certain cases may not mean absence but may represent the technical difficulties encountered in this work. In three patients with chronic ulcerative colitis there were homologous antigens for this serum. In one of these patients the serum reacted only with the homologous strain. In patients with lesions of the colon other than chronic ulcerative colitis agglutinins for one or more of the six antigens studied were found, in some instances in appreciable amount. In general agglutinins were found in higher titer in patients with ulcerating carcinomas of the rectum than in patients with minor lesions of the colon. In thirty-six patients in which the colon appeared normal on proctoscopic examination, Bacterium nephrophorum was not found and agglutinins for three of the antigens were absent from the serum.

Cutaneous Reactions to Tobacco.—The incidence of cutaneous reactions to tobacco was studied by Harkavy in (1) 400 normal smokers, male and female, (2) 126 adult female non-smokers, (3) 319 control smokers consisting of forty-seven normal persons and 292 adult patients suffering from various ailments, (4) 140 patients with thrombo-angiitis obliterans, (5) thirty-one patients with peripheral vascular disease associated with arteriosclerosis and (6) 100 patients with coronary disease

and angina pectoris. These studies indicate that positive cutaneous reactions to tobacco (prepared according to a method that the author describes) represent a true immunologic response. This was demonstrated by (1) the presence of tobacco reagins in patients reacting positively, (2) specific absorption of these reagins by corresponding tobacco allergens in patients with multiple sensitization and (3) the induction of a characteristic local eosinophilic reaction in the immediate urticarial response in patients with thrombo-angiitis obliterans, coronary artery disease and migrating phlebitis tested intradermally with tobacco. This is further attested experimentally, in that in about 33 per cent of male rats given daily injections by the intraperitoneal route, with the same tobaccos employed in testing the patients, gangrene of the toes developed. These animals were shown to be sensitized to tobacco by the Schultz-Dale technic. Of the 140 patients with thrombo-angiitis obliterans tested with ragweed and timothy pollen, horse dander and tobacco 68 per cent gave positive reactions to tobacco only of 1 plus and over, and 44 per cent gave plus-minus reactions, making a total of 78 per cent, tobacco only. This is in contrast to 9 per cent of reactions to tobacco only in the 400 normal control smokers. Twelve patients with thrombo-angiitis obliterans tested with nicotine tartrate 1:10,000 and 1:5,000 gave completely negative reactions. Of the 100 patients with coronary artery disease and angina pectoris 44 per cent reacted to tobacco and ten of fourteen had reagins to tobacco. The author infers from these observations that tobacco allergy plays an important part in certain forms of vascular disease as well as in symptoms referable to other systems such as the respiratory, gastrointestinal and cutaneous. The positive reactions assume etiologic significance since they can be correlated with the fact that in the patients studied, particularly in those with thrombo-angiitis obliterans or angina pectoris with or without coronary artery disease, discontinuance of smoking causes an arrest in the progress of the disease and resumption calls forth an exacerbation of all symptoms. Although it has been impossible to adduce any demonstrable proof of sensitization to nicotine as such, the question of hypersensitivity to its alkaloid on theoretic grounds cannot be dismissed completely. Sensitivity to drugs and chemicals may exist irrespective of the pharmacologic action of nicotine in all probability plays an accessory part through its constrictive influence on blood vessels involved. Such a result, common in all smokers, is, however, transitory in normal persons. In itself it evokes no notable symptoms, but it may become of utmost importance in the evolution of pathologic tissue changes in persons allergic to tobacco. In the latter, tobacco hypersensitivity may possibly intensify the pharmacologic action of nicotine. The immunologic and clinical evidence presented suggests that tobacco has an inciting role in thrombo-angiitis obliterans and in certain types of coronary artery involvement.

Radiation for Bladder Tumors.—Colby used the million volt x-ray generator in the treatment of eight malignant bladder tumors. Favorable effects from its use, as with other forms of high voltage therapy, in causing tumor regression have been

evident. Likewise, disappointments have been encountered in other tumors, which seem to be "radioresistant." Patients seem to tolerate this high voltage and short wavelength, showing less general reaction, x-ray sickness and cutaneous change than with lower voltages. Screening sufficient to cut out the rays delivered by the 200 kilovolt machine eliminates the destructive effect of the longer waves, so that larger doses with deeper penetration are employed without untoward results. The author considers wide surgical excision the most suitable treatment for malignant tumors of the bladder, and when possible circumscribed growths are removed by operation. He advises supervoltage radiation only when the extent of the tumor renders operation impracticable or other factors make surgical intervention unwise. Usually debilitated patients with extensive disease are irradiated. Although his series is entirely too small for a fair evaluation of this form of treatment he states that certain tumors appear profoundly affected, with considerable regression. Those portions of the tumor which project into the bladder cavity seem to be affected considerably more than those which have extended through the wall of the bladder. Other tumors are affected little, if at all, and are considered "radioresistant." The dosage so far employed is probably considerably less than that which is possible, but more experience is necessary to standardize dosage and determine its ultimate effect.

Increased Serum "Acid" Phosphatase in Carcinoma.—From their experience and from the reports in the literature (forty-four cases in all), Robinson and his colleagues conclude that increased serum "acid" phosphatase activity is consistent and specific enough in occurrence to be helpful in the differential diagnosis of prostatic carcinoma with skeletal metastases. The determination of serum "acid" phosphatase activity appears to be a useful supplement to the clinical and x-ray study of patients with prostatic carcinoma, particularly if surgical procedures are contemplated. The presence of increased serum "acid" phosphatase activity in patients with prostatic carcinoma implies dissemination of the primary tumor and in this sense has an unfavorable significance; an upward trend in serum "acid" phosphatase values may signify further metastatic involvement. The serum phosphatase activity in sixteen of the nineteen cases of prostatic carcinoma with skeletal metastases that they examined was found to exceed 3 units per hundred cubic centimeters. In thirteen cases of prostatic carcinoma without x-ray evidence of metastases to bone and in six cases of benign prostatic hypertrophy the values were within normal limits.

Modified Convulsive Therapy for Psychoses.—Hackfield and Halvorsen outline a modified form of convulsive therapy (massive dose plus postconvulsive sedation) adapted to the involutional depressive psychoses. The treatment was necessitated by the high incidence of this psychosis in the upper age brackets and as a means of preventing thoracic vertebral fractures and other complications. The modification was used in thirty-six cases. No preliminary preparation of the patient is necessary, and treatment may be given even after the patient has eaten. It promotes a gain in weight, and its relaxing effect facilitates sleep. Restraints are contraindicated, if the patient is placed on his back with the head flat on the bed and a pillow under the midthoracic region, the upper extremities in adduction, flexion and internal rotation and the lower extremities in full extension and adduction. The recommended dose of from 3 to 5 cc. of metrazol is inadequate. In the modified technic for patients with pronounced depressive-stuporous states the initial dose is 7 or 8 cc.; for those with marked apprehensive-agitated features from 10 to 12 cc. is used. With this dosage the subconvulsive reaction is eliminated; when it is encountered, a second administration with an increase of 2 cc. above the initial dose produces a satisfactory convulsion. Immediately after the convulsion 3 or 4 grains (0.2 or 0.26 Gm.) of sodium amytal intravenously or a hypodermic of one-fourth grain (0.016 Gm.) of morphine eliminates postconvulsive anxiety, uncontrolled thrashing during the postconvulsive stupor, nausea, headache and muscle spasm and effects complete amnesia for the treatment. The patient awakens from this sedation in from one-half to two hours, and he is given a hot bath and an alcohol rub. Throughout the treatment psychotherapy is utilized with appropriate emphasis on any apprehensive features regarding the treatment. The number of convulsions (induced every other day) necessary to initiate a remission varies with the psychopathologic features predominating. Patients in a pronounced depressive-stuporous state may respond with a remission after two or three convulsions, whereas those with hypochondriac symptoms predominantly of the anxiety type with delusional elements require on an average of from ten to twelve treatments. The delusional, depressive and hypochondriac features resolve, but psychotherapy

is required for the anxiety-compulsive elements that remain. If in this type of patient the remission is not satisfactory, a rest of a week followed by another course proves more satisfactory than a prolonged series of continued convulsions. A remission was induced in each of twenty-four private patients, but relapses occurred in two cases, in one of which the condition was successfully controlled by further treatment. Of the twelve state hospital patients nine showed remissions, one of whom relapsed, and three showed improvement.

Treatment of Botulism.—From his experience in treating sixteen cases of botulism, with a mortality of 30.25 per cent, Watson feels that botulinus antitoxin is imperative, regardless of the duration of the symptoms or the time elapsed from the ingestion of the toxigenic food, and furthermore that large initial intravenous doses of antitoxin diluted in dextrose-saline solution with epinephrine added should be followed by repeated intramuscular injections. The total quantity of antitoxin should depend on the severity of the intoxication and the apparent clinical response to treatment. The author believes that purified type-specific antitoxin would be preferable to the unpurified mixed antitoxin that he has used. Uncontrollable reactions and serum sickness were not encountered in the sixteen cases. In seven of the patients there developed respiratory paresis, requiring use of the respirator. One of these patients refused to be placed in the respirator and died, four who were in the respirator for varying periods died, and two completely recovered. The impression is that early arrangements should be made for respirators and that the apparatus should be brought to the patient, as his already weakened condition is aggravated by transportation. It appears to the author that the case mortality in botulism should be reduced from its former standard of from 60 to 70 per cent to a level of 30 per cent or less by the early administration of antitoxin and artificial respiration. These patients should be observed closely for clinical evidence of progress of the disease, and severe toxicity manifested by dysarthria, dysphagia, dyspnea, cyanosis, atelectasis or persistent vomiting should be considered a grave prognostic sign.
